always possible to obtain it. Next to this, that which has been boiled* may be recommended, and, if there is suspicion of organic impurities, this operation may be preceded by the use of permanganate of potash, or other well known oxidizing agents. If we may rely upon the recent experience of Champouillon,† the mere admixture of a small proportion of claret might be expected to effect the same result by rendering any organic impurities which may be present insoluble.

Various opinions have been expressed as to the quantity and temperature of the drinking water allowed in cases of acute dysentery. Celsus‡ taught that if there be fever the water should be warm, and that if the disease persists, very cold water should be given, because it astringes the ulcers and so commences a cure; but the latter opinion has long since been abandoned. Sennertus§ held that all drinks should be very sparingly administered. On the other hand, during the last century several physicians advised the use of water in large quantities, under the idea that it diluted and washed away the acrid contents of the intestinal canal. Thus Degner declared moderately cold water used freely to be one of the most potent remedies for dysentery. Huxham advised it to be drunk quite cold in large quantities. Tissot and Zimmermann‖ equally lauded the free use of water, but advised it to be drunk warm; indeed the latter declared that cold drinks are always noxious at the beginning of the disorder; his opinion in this respect has been repeated by some of the most accomplished modern writers on dysentery, such as Naumann and Bamberger; while Heubner¶ explains that cold drinks always bring on painful contractions in the transverse colon. This is undoubtedly true in some cases, and then, of course, cold drinks must be avoided; but it is far from being a general rule. Indeed, when there is no irritability of the stomach, ice water in small quantities, frequently repeated, is often quite as innocent as it is agreeable to the patient. When the stomach is irritable, ice-cold carbonic-acid water cautiously administered is often of service in allaying the gastric disorder;** and morsels of cracked ice allowed to melt in the mouth afford a great comfort to the patient, even when drinks of all kinds are rejected. The best rule as to the temperature of the drinks is to select that which is most agreeable to the patient, and as to quantity, to administer small portions frequently rather than to permit large draughts to be swallowed at a time. The notion that the disease could be, so to speak, washed away by the mere quantity of fluid swallowed has been deservedly abandoned.

---

* WHITWELL—*loc. cit.*, p. 603, *supra*—has recommended that the water supplied to dysenteric patients should be boiled, to get rid of the mica scales he supposes to do so much mischief, and DOUNON—*Suppression de la dyssenterie par l'ébullition de l'eau*, L'Abeille Médicale, An XXXV, 1878, p. 61—to kill the anguillula stercoralis and other parasites supposed to cause Cochin-China dysentery; see note ‡, p. 372, *supra*. I approve heartily of the measure without accepting these reasons for it.

† *Loc. cit.*, p. 613, *supra*.

‡ CELSUS—Lib. IV, Cap. 15, Vol. I, p. 297, Ed. cited p. 656, *supra*. AMATUS LUSITANUS—Cent. 2, Cur. 46, p. 289, Ed. cited p. 656, *supra*—has related a case of bilious dysentery in which ramenta had already made their appearance in the stools, but which was cured by copious draughts of cold water without any other treatment.

§ SENNERTUS—T. III, p. 184, Ed. cited p. 645, *supra*: "Paree bibere præcipuum auxilium est."

‖ DEGNER—Cap. III, § 77, p. 191, *op. cit.*, p. 625, *supra*: "Nullum est in natura remedium, quod, si potens sit in agendo, non etiam noceat, si perverse adhibeatur." He advises that the water should be boiled, and states that he himself, while suffering from a "diarrhœa bilioso-fœtida," drank, with advantage, 24 pints (libras) of tepid water in a single day; two days later, 48 pints within 14 hours, and again, still later, between 24 and 30 pints in 2 hours. No wonder ZIMMERMANN—*loc. cit.*, *infra*—exclaimed "a heroic stomach is required to support a deluge of this kind." According to HUXHAM—*De aëre et morb. epidem.*, 1743, in Opera Phys.-Med., Leipsic, 1764, p. 302—there is no disease in which diluent and demulcent drinks are more demanded than in dysentery, and he declares that he has cured cases with no other remedy than this (with a little opium added, however) after the patient had been suitably purged. TISSOT—T. III, p. 10, *op. cit.*, p. 625, *supra*—asserted that he had cured many dysenteries by administering a cup of tepid water every quarter of an hour without any other remedy. ZIMMERMANN—Cap. IV, S. 71, *op. cit.*, p. 648, *supra*—repeats this statement upon the basis of his own experience, and affirms that water copiously drunk is a universal remedy in dysentery as well as in fevers.

¶ M. E. A. NAUMANN—Bd. IV, Abth. 2, S. 77, *op. cit.*, p. 645, *supra*; BAMBERGER—S. 409, *op. cit.*, p. 578, *supra*; HEUBNER—S. 542, *op. cit.*, note *, p. 529, *supra*.

** FOURNIER et VAIDY—p. 390, *op. cit.*, p. 362, *supra*—recommended "de l'eau gazeuse de Seltz ou de Spa, avec un peu de vin," during convalescence from dysentery; without the wine, these or any natural carbonic-acid waters devoid of active medicinal properties, or the artificial carbonic-acid water, may be drunk at any stage of the disease; the natural purgative waters also prove serviceable in cases in which such remedies are indicated.

With regard to the use of *coffee* and *tea*, it may be said that there is no reason to believe them injurious, provided they are acceptable to the patient. Even in the early stages of acute dysentery, when astringent medication is most to be deprecated, it is improbable that they do any harm unless given too strong or in excessive quantities. Indeed, according to Roché, coffee, with sugar but without milk, taken frequently in moderate quantities, is a valuable remedy for dysentery; and more recently Savignac, without adopting this view, has expressed himself favorably with regard to the use of black coffee in that disease.* Strong tea, as it is still more advantageous than coffee when astringent remedies are desirable, is still more objectionable when they are contraindicated; yet if reasonably diluted it may be used with impunity in most cases. Naumann testified that he cured himself of a mild attack of dysentery with black tea, taken with a little sugar and milk; and Savignac preferred an infusion of tea to any other habitual drink for dysenterics.†

As for *Alcoholic beverages*, there can be no doubt that some of the fermented drinks, such as beer, ale, cider and the like, should as a rule be avoided.‡ Although, as has already been shown, there are no valid reasons for charging these drinks with causing the fluxes, yet they so generally disturb the bowels when already diseased that they ought to be proscribed in all acute cases, and in chronic cases, except when they are earnestly desired by patients accustomed to their use and are found on trial not to disagree. Well selected wines, on the other hand, and even distilled liquors, have a considerable range of utility, particularly in acute dysentery and in the chronic fluxes. The Greek physicians attached considerable importance to the use of wine in dysentery, especially after the strength of the patient began to fail. They gave the preference to the red wines, or in a general way to astringent and austere wines, and used them at first much diluted with water or other liquids, afterwards, if necessary, pure.§ With comparatively few exceptions this practice was followed by the best instructed practitioners until the middle of the last century,‖

---

* J. U. E. von Reider—*Untersuch. über die epidem. Sumpffieber*, Leipsic, 1829, S. 181—advised the use of strong coffee, without sugar or milk, in obstinate dysentery. Hargens—*Ueber die epidem. Constitution zu Kiel*, &c., 1798, Hufeland's Jour., Bd. VII, St. 3, 1799, S. 154—used, under certain circumstances, strong coffee without milk; (nothing is said of sugar.) The observations of Roché, referred to in the text, were communicated in a letter dated June 12, 1822, to Foderé—*Leçons sur les Épidémies*, &c., T. II, Paris, 1823, p. 102—who seems to have been prudently skeptical as to the active virtues attributed to this drink. Savignac—p. 471, *op. cit.*, p. 620, *supra*—remarks: "Le café, qui a un mode d'action physiologique, et à l'occasion, thérapeutique, très-analogue à celle du thé, me paraît généralement utile. Mais je repousse le café au lait, qui peut favoriser la diarrhée, et je préfère le café noir."

† Naumann—S. 77, *op. cit.*, p. 645, *supra*. Savignac—*loc. cit.*, last note—states that the drink he habitually prescribes to dysenterics is an infusion of tea which he sweetens with syrup of quinces and administers warm.

‡ Already Fabricius Hildanus—p. 679, *op. cit.*, p. 644, *supra*—counseled against the use of beer in dysentery, and Hoffmann—T. III, p. 156, *op. cit.*, p. 647, *supra*—was of the same opinion. Sennertus—T. III, p. 184, *op. cit.*, p. 645, *supra*—on the other hand, permitted the use of good beer; Sydenham—Vol. I, p. 180, transl. cited note †, p. 407, *supra*—gave his patients beer slightly warmed, even during the first days of the disease, and Geach—*Some Obs. on the present epidemic Dysentery*, London, 1781, p. 36—declares that during the Plymouth epidemic he permitted his patients to drink either beer or cider, and saw no ill consequences result. Most modern physicians will, I suppose, agree with the view expressed in the text, though it is probable, as Savignac—pp. 464–5, *op. cit.*, p. 620, *supra*—admits, that those who are accustomed to the free and habitual use of these beverages may use them with impunity. I need not add that this writer objects as a general rule to the use of beer, and especially of cider: see his views in the note just cited. Heubner—S. 547, *op. cit.*, note *, p. 529, *supra*—mentions "warm beer" among the stimulants that may be given in the exhaustion of diphtheritic cases. I can hardly assent to this practice.

§ In the Hippocratic treatise, *De Morb. Vulg.*, Lib. VII, § 3, [Ed. Littré, V, p. 369 *et seq.*,] will be found an account of a case in which red wine was used after the first few days of the disease. Ætius—*loc. cit.*, p. 658, *supra*—recommends wine only after the strength begins to fail; it should be astringent, but not very old. Alexander of Tralles—Lib. VIII, Cap. 8, p. 433, Ed. cited p. 624, *supra*—permitted the use of astringent wine in rheumatic dysentery; in dysentery with ulceration of the intestines—Cap. 9—he recommended wine mixed with water so soon as the strength of the patient begins to fail, p. 459; but if there be reason to think the disease proceeds from phlegm, the pure wines should be given: "Et vinum exhibendum Sareptinum, aut Tyrium, aut ex his quæ in Campania nascuntur, Britianum aut Palmatianum," p. 460. Paulus Ægineta—Vol. I, p. 527, transl. cited on p. 624, *supra*—says: "When the stomach is languid, wine may be taken." Celsus—p. 297, Ed. cited, p. 656, *supra*—speaks of the use of "light, austere wine" only as a substitute for astringent drinks.

‖ Thus Sennertus—T. III, p. 184, *op. cit.*, p. 645, *supra*—recommends the use of red, astringent wine mixed with pure water, or water in which red-hot iron or gold has been extinguished, so soon as the strength of the patient begins to fail, and remarks that if the digestive powers are debilitated the use of wine is always advantageous, sometimes even necessary. Fab. Hildanus—Cap. 7, p. 679, *op. cit.*, p. 644, *supra*—permitted the use of red, astringent wine under the same circumstances, though he counsels against the use of wine so long as there is fever or inflammatory symptoms. Even Sydenham—*loc. cit.*, note ‡, *supra*—if the strength of the patient was "much pulled down," advised "half a pint of Canary wine, boiled along with a quart of water, and cooled," to be used as an "ordinary drink." Hoffmann—*loc. cit.*, note ‡, *supra*—advised "sub finem morbi, ad intestina roboranda, haustus vini generosi;" and Degner—p. 195 *et seq.*, Ed. cited p. 625, *supra*—advised throughout the disease, even if fever be present, the use of the subacid wines of the Rhine and the Moselle; but he thought generous and sweet wines, such as those of Spain, were not well borne, and objected to the red, astringent wines of France, especially in the beginning of the disease.

when the energetic protests of Zimmermann led a considerable number of physicians to regard with distrust the use of alcoholic beverages in this disease, and either to administer them with great caution or to abandon them altogether.* This view was adopted subsequently by Broussais and his school† as a part of the rigid antiphlogistic treatment which they employed in dysentery; but a certain number of practitioners always adhered more or less closely to the old practice,‡ which in recent times has secured the confidence of some of the most approved writers on this subject.§

In ordinary acute diarrhœas these remedies are quite unnecessary, and the popular practice of indiscriminately administering whiskey or brandy, with or without aromatics, for simple attacks of this disorder not unfrequently aggravates the inflammation and transforms a trifling into a serious affection. In acute dysentery, whether of the catarrhal or of the diphtheritic kind, stimulants of every sort should be avoided at the commencement of the disease, and in the catarrhal form they can often be advantageously dispensed with in all its stages; yet we may still with advantage hold fast to the practice of the ancients, and begin the administration of stimulants in either variety of dysentery so soon as the strength of the patient begins to fail. This may occur in any severe or protracted case, but it is especially likely to happen in the diphtheritic cases after sloughs have formed, and during the process of separation; stimulants are then required precisely as they are in external gangrenous processes, and should be liberally administered. Claret mixed with water may often be advantageously used as a drink before the stronger wines are needed. Sherry and other generous wines should be diluted with whey or water when first employed. Later in the disease, brandy or whiskey may be given mixed with milk, or in the form of toddy. In all cases care should be taken to proportion the quantity of alcohol given, whatever be its form, to the actual wants of the patient; nothing is gained by the administration of excessive potations; at the same time the significance of alcohol as food should be borne in mind in those cases in which other food is rejected, or only tolerated in insufficient quantities. When distilled liquors are used for this purpose they should, as

* We have just seen—in the last note—that FABRICIUS HILDANUS objected to the use of wine, if fever or signs of inflammation be present, and we learn from DEGNER—same note—that some of the physicians of his own time, whom he declares to be "morbi genium ignorantes," argued against its employment. Sir JOHN PRINGLE—*Obs. on the Dis. of the Army*, Part III, Chap. 6, in his first edition, London, 1752, p. 287—does not refer to the question of the use of stimulants, except to say that his patients were not allowed "small beer" even during convalescence. In his 3d edition, London, 1761, p. 247, he says he allowed his convalescents "water with a spoonful or two of rum or brandy to a pint." In his 4th edition, London, 1764, p. 291, he seems to have repented even of this indulgence, declaring, "I allow of no fermented liquor, nor spirits," and this statement is repeated in subsequent editions: *vide* 7th ed., London, 1774, p. 285. It was, however, undoubtedly the great authority of ZIMMERMANN—Cap. 7, S. 160 *et seq.*, *op. cit.*, p. 648, *supra*—that gave currency to the opinion that it was best to abstain from alcoholic beverages. He declared that in the Swiss epidemic both wine and brandy proved altogether noxious; classed them, on account of their ill effects, with aromatics and astringents, as things to be wholly avoided, and severely censured the domestic mixtures of ginger, pepper, wine, brandy, &c., employed by the peasantry.

† BROUSSAIS—T. III, p. 208 *et seq.*, *op. cit.*, p. 643, *supra*—adopted in the treatment of dysentery an antiphlogistic regimen so rigid that he declared even rice-water too irritating: "L'eau de riz serait encore trop irritante, parcequ'elle exige un léger travail digestif;" of course he ordered "l'abstinence des boissons stimulantes," p. 209, and declared that even after the tenesmus and tormina had subsided, indulgence in wine provoked the disease to new progress, p. 218. Yet it is worthy of note that BROUSSAIS himself recommended the cautious use of wine in chronic cases; it should be good, used in small quantities and only with the meals; at first it should be diluted with water, afterwards it might be used pure, but only a little at a time, as long as any traces of general *éréthisme* could be recognized, p. 226.

‡ Thus PINEL—T. II, p. 334, *op. cit.*, p. 605, *supra*—advised the use of wine when dysentery is complicated with adynamic fever, and in the chronic cases, p. 337. FOURNIER et VAIDY—p. 390, *op. cit.*, p. 362, *supra*—permitted a little wine during convalescence, preferably the generous wines of the south rather than the acid wines of the north, but they declared that it is necessary to be very circumspect in the use of wine. ANNESLEY—Vol. II, p. 299, *op. cit.*, p. 621, *supra*—permitted a little wine in the advanced stages of dysentery, "especially in the cases of those who have been in the habit of using spirituous and intoxicating liquors." In chronic diarrhœa and dysentery he declares "wine ought not to be exhibited, unless the powers of life require to be rallied. We have seen the too early permission to take a single glass of wine bring back the acute symptoms, and have often witnessed the chronic forms of the disease converted into the acute by such imprudence," p. 383. According to HAUFF—S. 438, *op. cit.*, p. 534, *supra*—wine is as a rule injurious in dysentery; a single teaspoonful will often produce abdominal pain; nevertheless in certain cases it is advantageous; thus in primarily typhous dysentery the red or white wines may be required, S. 452; in the nervous paralytic cases, mulled wine or punch, S. 454; and in chronic dysentery, good old red wine, S. 455. VOGT—S. 162, *op. cit.*, p. 645, *supra*—permitted the use of good red wine even before convalescence sets in, and declares that although sometimes it irritates the intestine and provokes fever, yet very often it is well borne, and acts as a genuine restorative to the patient.

§ For example, SAVIGNAC—p. 463, *op. cit.*, p. 620, *supra*—although he declares "les vins et les alcooliques ne conviennent que médiocrement aux dysentériques," points out that there are many exceptions to this rule, and advises wines, "even generous wines," whenever there is notable adynamia, and during convalescence. HEUBNER—S. 547, *op. cit.*, note *, p. 529, *supra*—to support the failing strength, in diphtheritic cases, recommends grog, punch, wine soup, &c.

a rule, be so diluted that the alcohol shall not exceed twenty to twenty-five per cent. of the mixture. Only in extremely adynamic conditions, when the stomach is not irritable, and especially in the case of patients accustomed in health to the habitual use of these drinks, does it seem prudent to use whiskey or brandy undiluted.* In the chronic fluxes some kind of alcoholic drink is very generally useful, especially when taken in connection with the food. The selection and quantity must be determined by the degree of general debility and the condition of the digestive processes. Claret and water will be sufficient for some cases; others will require the stronger wines or the alcoholic liquors.

The general principles thus sketched were followed by many of our best medical officers during the civil war. There were, however, not a few who were too apt to look upon every serious case of flux as one of "chronic diarrhœa," and to prescribe stimulants forthwith. It is not possible to determine from the records the extent of this error, or to give numerical expression to the evil effects which undoubtedly resulted.†

THE FOOD.—It should be remembered that in all the intestinal fluxes the digestive powers are diminished, and this in proportion to the severity of the disease. Lesions of the functions in question become especially marked in acute diarrhœa or dysentery when accompanied by fever, and in diphtheritic dysentery, whether fever is recognizable or not. In severe cases of diphtheritic dysentery the disorder may even amount to complete abolition of the digestive functions, and between this extreme apepsia and the most trifling diminution in the digestive activity all degrees exist. It is therefore the duty of the physician in every case to observe the condition of the patient in this respect, and to proportion the quantity and character of the food to his digestive capabilities.‡ Some of the physicians of antiquity recommended total abstinence during the first day or two of an attack of acute dysentery,§ and it must be admitted that during this period it is advantageous to reduce the food to a minimum both in dysentery and in serious cases of acute diarrhœa. At this time barley water, rice water, gum water or other *feebly nourishing drinks* may be prescribed with advantage, and their use may be continued for some time during the subsequent progress of the disease, if they are relished by the patient, though not to the exclusion of more nourishing food.

A great variety of these drinks were prescribed by the physicians of antiquity, most of which have fallen into disuse, while some are still employed at the present time.‖ They were believed to dilute the acrid humors in the alimentary canal, thus rendering them less

---

* In this I agree with the cautious advice of UFFELMANN—p. 259, *op. cit.*, p. 388, *supra*.

† On the use of alcoholic drinks in acute dysentery during the civil war, see, in Sect. II, the reports of COUES, p. 64; MULFORD, p. 80; W. H. BROWN, p. 81; WALTON, p. 93; and COFFMAN, p. 97. In chronic dysentery, STORROW, p. 43. In "diarrhœa," POTTER, p. 83; HILL, p. 88; TOMPKINS, p. 90. Compare also the reports of these cases, in Sect. III, in which the treatment is recorded, *e. g.*, cases 203, 206, 213, 216, 224, 247, &c.

‡ GALEN so well appreciated these digestive difficulties that he declared—*De Remediis Parabilibus*, Lib. I, Cap. 13, [Ed. Kühn, XIV, p. 379.]—that the very best remedy for dysentery is a scanty diet, and that whatever is given should be easy of digestion. ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 434, Ed. cited p. 624, *supra*—wrote: "A dysenteric, on account of the imbecility of the stomach and intestines, cannot digest much, especially when he has fever." UFFELMANN—*op. cit.*, p. 388, *supra*—in a suggestive essay, has recently attempted to discuss this digestive debility in the light of modern physiological knowledge.

§ Thus ALEXANDER OF TRALLES—p. 435, Ed. cited last note: "Primis duobus diebus abstinentiam indicimus."

‖ Barley water, prepared by boiling husked barley, with or without the addition of small quantities of other substances, may be taken as the type of these preparations. Under the designation ptisan its use in acute diseases is treated at great length in the Hippocratic treatise *De Victus Rat. in Morb. Acut.*, [Ed. Littré, II, p. 245 *et seq.*] GALEN regarded it as worthy of a special work—*De Ptisana Liber*, [Ed. Kühn, VI, p. 816,]—and thought it possessed detergent and lubricating, as well as nutritive, properties. The modern French physicians give the name of tisanes not only to these drinks and others referred to in the text, but to various infusions and decoctions of herbs, &c. Among other demulcent and subastringent drinks recommended by GALEN in dysentery, I may mention decoction of rice with plantain—*De Rem. Parab.*, Lib. I, Cap. 13, [Ed. Kühn, XIV, p. 380,]—decoctions of pomegranates and quinces—*loc. cit.*—and decoction of marsh-mallow (althæa)—*De Simpl. Med. Temp. ac Fac.*, Lib. VI, Cap. 5, [Ed. Kühn, XI, p. 867:] it would be easy to name various others. ALEXANDER OF TRALLES—p. 440, Ed. cited p. 624, *supra*—gave special directions for the use of ptisan in dysentery, and under certain circumstances mixed honey with it. He also advised in the early stages of the disease the use of decoctions of rice, spelt and other farinaceous articles, strained and mixed with a little milk, &c. Among more modern writers, compare the remarks on the use of such substances by FAB. HILDANUS—p. 679, *op. cit.*, p. 644, *supra;* SENNERTUS—T. III, p. 183, *op. cit.*, p. 645, *supra;* and FRID. HOFFMANN—T. III, p. 156, *op. cit.*, p.

irritating; to wash away the intestinal contents and cleanse the ulcerated surfaces; while the more mucilaginous and glutinous preparations were supposed to sheathe the mucous membrane, and thus to protect it against further erosion or abrasion by the humors that might subsequently descend; for this latter purpose fatty matters of various kinds were occasionally prescribed; moreover great importance was attached to the addition of various fruits and herbs believed to be possessed of mild astringent properties.*

These views have for the most part entirely lost credit. The admixture of astringents is not to be thought of except under circumstances to be discussed hereafter, when astringent medication is indicated, and I presume that at the present time most physicians will agree with Savignac† in regarding the other supposed results as altogether illusory. So far as any diluent or cleansing effect is concerned, these drinks can only act in virtue of the water they contain, and as this is rapidly absorbed in the stomach or upper part of the small intestine, they cannot be expected to exercise any perceptible influence upon the mucous membrane of the colon. Indeed, if we may judge from the earnestness with which they insisted upon the simultaneous use of the same fluids as enemata,‡ the Greek physicians must themselves have been aware that the effects hoped for are not fully obtained when diluent or emollient liquids are given by the mouth alone.

So, too, any protective sheathing of the mucous membrane by the administration of glutinous or fatty substances must, at present, be regarded as in the highest degree improbable. The starchy, saccharine, gummy and fatty substances which may be used for this purpose are not merely modified by the digestive process to an extent varying with its activity in each individual case, but the undigested portions submit at the temperature of the body to divers fermentations and decompositions, the products of which may themselves exercise an irritating effect upon the inflamed mucous membrane. The beneficial effects of such drinks, then, beyond the introduction of so much water into the blood, which could be equally well effected by drinking water alone, depend merely upon the small quantities of nourishment they contain, and upon the fact that this nutriment is the more manageable by the enfeebled digestive organs because it is presented in a liquid form. Any excess in the amount of the alimentary principles thus administered beyond what can be completely digested is to be regarded as altogether injurious.

Among the articles of this class the *white decoction* of Sydenham long enjoyed a great reputation. It consisted of two ounces each of bread crumbs and calcined hartshorn,

---

647, *supra*. DEGNER—Cap. III, § 61–69, p. 169 *et seq.*, *op. cit.*, p. 625, *supra*—attached extreme importance to a decoction of salep; ZIMMERMANN—Cap. V, S. 82 *et seq.*, *op. cit.*, p. 648, *supra*—to barley water, which he gave in large quantities, adding often an ounce of cream of tartar to each quart. FAB. HILDANUS—p. 676, *op. cit.*—lauded especially the use of an emulsion of sweet almonds, and this preparation long enjoyed considerable popularity, but was finally abandoned on account of its tendency to undergo fermentation in the alimentary canal. Solutions of gum Arabic and tragacanth, employed already by the Greek physicians, (see ÆTIUS—Tetrab. III, Serm. I, Cap. 47, p. 609, Ed. cited p. 644, *supra:* "Obtundit autem tragacanthus et gummi,") were recommended by the Arabians (see AVICENNA—Lib. III, Fen 16, Tract. 1, Cap. 4, p. 817, Ed. cited p. 632, *supra)* and the majority of subsequent physicians, among other preparations of this class, but acquired undue importance from the teachings of BROUSSAIS—T. III, p. 213, *op. cit.*, p. 643, *supra*—who thought even rice water too irritating. It may well be doubted whether these solutions possess any advantage over so much water. Various mixtures containing wax as their base have also enjoyed considerable reputation. DIOSCORIDES—Lib. II, Cap. 105, Paris, 1549, fol. 98—mentions this use of wax as well known in his time: "Datur in sorbitione dysentericis." It may be dissolved in hot milk, or made into a mixture by the aid of gum Arabic or soap. DEGNER—Cap. 3, § 88, p. 220 *op. cit.*—cites a number of authorities according to whom the preparation with milk exercised a marked curative effect, especially in camp dysentery. PRINGLE—Part III, Cap. 6, p. 273, Ed. cited p. 640, *supra*—mentions other authorities in its favor, and also states that HUCK had used a mixture, in which soap was used as a dissolvent of the wax, with good effects in treating dysentery in the British military hospitals in North America. Several formulæ for making emulsions of wax with the aid of gum Arabic, &c., are cited by NAUMANN—Bd. IV, Abth. 2, S. 82, *op. cit.*, p. 645, *supra*—who, however, was too well instructed to attribute any importance to their use, and expressed the opinion that the chief benefit to be expected from them was the exclusion of more dangerous medication; "man, indem man ihnen vertraute, um so eher von den gefährlichen adstringirenden und anderen gerühmten Specificis die Hand entfernt hielt."

* These indications, which will be found more or less fully expressed in almost all the older medical writings on dysentery, are nowhere more clearly expounded than by VAN SWIETEN—*Comm. in H. Boerhaave Aphorismos*, T. II, Leyden, 1745, § 722, p. 388—who points out that water is indeed the only diluent in these cases, but that various saponaceous, emollient, oily and earthy substances are added to it in accordance with the nature of the irritating acrimony supposed to exist in the bowels.

† SAVIGNAC—p. 468, *op. cit.*, p. 620, *supra*. ‡ See the remarks on enemata, *infra*.

boiled in spring water from three pints to two, and sweetened with white sugar.* Disused in this country and Great Britain, it has continued to find favor in France, and Savignac declares it to enjoy the confidence of the French practitioners not merely as an aliment but on account of its medicinal virtues in both diarrhœa and dysentery.

Another preparation, of a more nourishing character, is the *solution of albumen*, suggested in 1835 by Bodin. It is made by beating up the whites of eggs with water, sweetening the mixture with white sugar and flavoring with some aromatic water. Extraordinary results are said to have been obtained from its use, especially by Mondière,† which have been explained by some as resulting from a supposed emollient action upon the mucous membrane of the large intestine, by others to its furnishing a form of nutriment especially adapted to replace the loss of blood albumen due to the presence of this substance in the dejections. Subsequent experience has not justified the extravagant claims made for this form of liquid food, but it undoubtedly offers some advantages in the alimentation of dysenteric patients, especially in cases in which milk is not well digested.

No article of diet played a more considerable part in the management of dysentery, as practiced by the ancients, than *milk*. It was given in the early stages of the disease in the form of whey, in which sometimes red-hot flints or pieces of iron were quenched, for the purpose of adding strengthening or astringent properties. Subsequently boiled milk, and still later in the disease unboiled milk was used. There was a choice in the kind of milk employed. That of goats was supposed to be tolerated before cows' milk, and cooked milk earlier than raw. The milk might be mixed with water or given pure. Honey might be added to increase its laxative and detergent properties, in virtue of which it was regarded as medicine as well as food. Barley, rice and other farinaceous substances were boiled in it to increase its nutritive value, and eggs were sometimes added for the same reason. It was fully recognized that under certain circumstances, especially at the beginning of dysentery, and when fever was present, milk was not well borne; but with these exceptions its use was regarded as a most important part of the treatment.‡

---

* SYDENHAM—*Med. Obs.*, Sect. IV, Chap. 3, Vol. I, p. 171, Ed. cited note †, p. 407, *supra*. The burnt hartshorn (which consists chiefly of bone phosphate of lime with a little free lime) had long been used as a remedy in dysentery: compare GALEN—*De Rem. Parab.*, Lib. I, Cap. 13, [Ed. Kühn, XIV, p. 380.] DAVID MACBRIDE—*A Methodical Introduction to the Theory and Practice of Physic*, London, 1772, Part II, Book III, Chap. 3, p. 468—mentions the white decoction of SYDENHAM among the articles of diet suitable for dysenterics. TROUSSEAU—*Clin. Méd. de l'Hôtel-Dieu de Paris*, 2me Éd., Paris, 1865, T. III, p. 171—states that he attaches great importance to its use. For the remarks of SAVIGNAC referred to in the text see p. 469, *op. cit.*, p. 620, *supra*.

† PAYEN—*Note sur la substitution de l'albumine au caséum*, Jour. de Chimie Méd., T. VI, 1830, p. 138—had previously recommended the use of albuminized water in the alimentation of the sick as a substitute for milk when this was not well digested by the patient. BODIN *(de la Pichonnerie)*—*Usage de l'eau albumineuse dans le traitement de la dysenterie*, Jour. des Connaissances Medico-Chirurgicales, An II, 1834-5, p. 309—recommended the whites of five or six eggs to the litre of water and an ounce and a half of powdered sugar, to be well shaken in a bottle; some bird shot are introduced into the bottle to facilitate the mixture; a little orange-flower water, mint or any agreeable flavor is added. The whole may be given in the twenty-four hours in divided doses. He often administered also three or four injections daily, composed each of the white of an egg beaten with water in the same way. J. T. MONDIÈRE—*Mémoire sur le traitement de la dysenterie par l'albumine donnée en boissons et en lavemens*, L'Expérience, T. III, 1839, pp. 97 and 113. This paper is illustrated by a number of cases successfully treated in the manner described above. The author remarks: "The efficacy of this treatment is such that we have seen very grave dysenteries yield in the course of 12 to 24 hours without leaving, so to say, a trace of their existence," p. 100. TROUSSEAU—*loc. cit., supra*—has commended the use of albuminized water in dysentery, and SAVIGNAC—*op. cit.*, p. 620, *supra*—who has discussed the subject with commendable prudence, concludes: "I do not, then, rely on the exclusive employment of albumen in the treatment of dysentery, but I have entire confidence in albuminous alimentation, one of the most rational deductions of the experimental physiology of digestion," p. 388. I may add that ÆTIUS—Tetrab. III, Serm. 1, Cap. 45, p. 608, Ed. cited p. 644, *supra*—mentioned the use of raw eggs in the alimentation of malignant dysentery; and that the albumen of eggs was commended as an injection in dysentery by AVICENNA—Lib. II, Tract. 2, Cap. 527, p. 367, Ed. cited p. 632, *supra*: "Et ex albumine quidem ipsorum fit clystere cum meliloto propter ulcera intestinorum, et putrefactionem eorum."

‡ The following references will serve to illustrate the statements of the text: A detailed account of a case of dysentery treated chiefly with milk will be found in the Hippocratic treatise *De Morb. Vulg.*, Lib. VII, § 3, [Ed. Littré, V, p. 369.] He took whey at first, then boiled asses' milk, and finally raw cows' milk; the quantity of milk used was about a litre daily. ARCHIGENES—in ÆTIUS, Tetrab. III, Serm. 1, Cap. 45, p. 604, Ed. cited p. 644, *supra*—recommended in the treatment of dysentery after the third day, if the fever permitted, the use of fresh milk mixed with honey, and we learn from CÆLIUS AURELIANUS—*Morb. Chron.*, Lib. IV, Cap. 6, Amsterdam, 1709, p. 526—that DIOCLES had advised the same mixture, attributing to it purgative qualities. PHILUMENUS—see ÆTIUS, Tetrab. III, Serm. 1, Cap. 35, p. 585—commended the use of recently milked cows' or goats' milk drunk warm, or milk in which heated stones or pieces of iron had been quenched, in diarrhœa and other alvine fluxes. See also the detailed account of the use of milk in dysentery in the *Natural History* of PLINY, Lib. XXVIII, Cap. 33. GALEN—*De Simpl. Med. Temp. ac Facultat.*, Lib. X, Cap. 2, [Ed. Kühn, XII, p. 267]—affirmed that whey, in which heated flints or cylinders of iron have been quenched, is the very best remedy for dysentery and all acrid fluxes from the bowels: milk could be advantageously treated in the same way. In the same chapter (pp. 291-2) he states that the addition to milk thus

Amatus Lusitanus (1557) appears to have been one of the first to raise his voice against its free employment. He emphasized the dangers of its use when fever is present, which had long before been insisted upon by Alexander of Tralles, and declared that it ought not to be given to those who have bilious stools, whether fever is present or not. These objections, fiercely combatted by some physicians, convinced many others.* Sennertus, who still adhered to the ancient practice, has left a dissertation in which the views entertained in his times by the conflicting parties are fairly summarized.† But, notwithstanding his advocacy, the employment of milk in dysentery was gradually abandoned. Hoffmann thought it should be only used when diluted with water and boiled. Pringle advised the admixture of lime water in case the milk by itself should "turn sour on the stomach." Zimmermann objected to using it at all,‡ and his example has been followed, until quite recently, by the majority of physicians in spite of the extravagant accounts given by Pouppé Desportes and Dalmas§ of the benefits they derived from its use in the treatment of fluxes in the West Indies. Indeed many modern physicians agree with Savignac|| in condemning it as positively injurious.

Pécholier has nevertheless revived the milk diet with considerable success, and still more recently it has been beneficially employed in the French naval hospitals for the treatment of cases of the chronic fluxes of Cochin China.¶ I confess I incline to believe that there are many other cases in which the ancient use of milk in the treatment of the fluxes might be revived with advantage. Mixed with lime water, it is often well borne

prepared of the fæces of dogs fed on bones only, makes a remedy for dysentery of quite wonderful virtues. This disgusting mixture was protested against by ALEXANDER OF TRALLES—p. 465, *op. cit.*, *infra*—who declared that it was unreasonable to use such substances when we have so many other less objectionable yet efficacious medicaments; but in spite of such intelligent criticism it still enjoyed the favor of physicians as late as the latter part of the 16th century. Compare NICOLAUS PISO—*De Cognoscendis et Curandis præcipue Internis Humani Corporis Morbis*, Lib. III, Cap. 15, p. 274, Frankfort 1580. In the treatise *Ad Pisonem De Theriaca*, Cap. 9, [Ed. Kühn, XIV, p. 241,] GALEN praises the use of cows' milk as advantageous in dysentery. His writings contain numerous other precepts with regard to the use of milk, both in the fluxes and other diseases, which the curious reader will find indexed under the heading *Lac* in the last volume of Kühn's edition. For a long time subsequent writers added little or nothing to these precepts. Compare ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 435 *et seq.*, Ed. cited p. 624, *supra*—who has treated of the use of milk in dysentery in his usual concise manner. He preferred goats' milk to all others, next that of the cow, the milk of the horse or ass being less esteemed. Especially has he emphasized the objections to the administration of milk if there is fever, because it acidifies or corrupts on the stomach. See also PAULUS ÆGINETA—Vol. I, pp. 521 and 526, Ed. cited p. 624, *supra*—and FAB. HILDANUS—p. 676, *op. cit.*, p. 644, *supra*—who commends the milk of a human female as best of all; "lac quoque muliebre summopere convenit."

* AMATUS LUSITANUS—Cent. II, Obs. 44, p. 287, *op. cit.*, p. 656, *supra*—based his opinion chiefly upon his own observation, declaring: "Et nos longa experientia, ita evenire sæpe observatum habemus:" but he cites the opinions of various writers in support of his view, particularly a passage from HIPPOCRATES—Aph. V, 64, [Ed. Littré, IV, p. 557,]—in which it is declared that milk ought not to be given to persons having headache, fever, bilious discharges in acute fever, &c. These views were vigorously criticised, among others, by ZACUTUS LUSITANUS—*De Med. Princip. Hist.*, Lib. II, Quæstio 46, Comm., Opera, Lyons, 1649, Vol. I, p. 333.

† SENNERTUS—T. III, p. 188, *op. cit.*, p. 645, *supra*, Quæstio 5: "An lactis usus in dysenteria conveniat?"

‡ HOFFMANN—T. III, p. 158, *op. cit.*, p. 647, *supra*—objected to pure milk in dysentery particularly on account of its tendency to coagulate in the bowels. PRINGLE—Part III, Chap. 6, p. 283, Ed. cited p. 640, *supra*—in the last edition of his work, favored the use of "a milk- and farinaceous diet," and complains that "in large hospitals, the soldiers cannot be fully supplied with milk;" it is only in the case mentioned in the text that he recommended that "a third part of lime-water" should be added—p. 284. ZIMMERMANN—Cap. IV, S. 72, *op. cit.*, p. 648, *supra*. Elsewhere—Cap. X, S. 426—he states that PRINGLE did not allow milk to his patients, even when convalescent, unless it was diluted with lime water, as he found that milk by itself had a tendency to increase the gripings. This view was indeed expressed by PRINGLE in his first edition—London, 1752, p. 287—but he lived to take a more favorable view of the use of milk, as has just been shown.

§ J. B. R. POUPPÉ DESPORTES—*Hist. des Maladies de St.-Domingue*, Paris, 1770, T. II, p. 106 *et seq.*—in speaking of the treatment of the hepatic flux, affirmed that there is no more salutary remedy than milk for the majority of patients; indeed, that "without it more than two-thirds of them would perish." Further on—p. 111—he speaks of the usefulness of milk in the alvine fluxes generally (des flux de ventre) and in convalescence from dysentery, &c. DALMAS—*Diss. sur une espèce particulière de diarrhée*, Paris Thesis, No. 147, 1808—claims to have used a preparation of milk and salep with great advantage in the "diarrhée scorbutique" of the Antilles, and relates in detail several illustrative cases.

|| SAVIGNAC—*loc. cit.*—remarks: "Zimmermann en défend formellement l'emploi, et je me range à son avis." He declares that nothing but inconvenience can result from giving it as a drink, even when diluted with water or any ptisan, and that although it may occasionally be given if demanded by the caprice of a patient, it ought not to enter into the habitual alimentation of dysenterics.

¶ G. PÉCHOLIER—*Des indications de l'emploi de la diète lactée dans le traitement de diverses maladies et spécialement dans celui des maladies du cœur, de l'hydropisie et de la diarrhée*, Montpellier Médical, T. XVI, 1866, p. 389, T. XVII, 1866, pp. 1 and 197. The first of these papers has an interesting summary of the history of the use of milk in medicine; the last refers particularly to its use in diarrhœa. LOUIS FLEURY—*Traitement de la dysenterie chronique*, Archives de Méd. Navale, T. XVI, 1871, p. 311—declared, a few years later: "Pour moi, le régime exclusivement lacté, continué pendant un temps plus ou moins long suivant les indications, constitue l'alimentation la plus convenable" for chronic dysentery. Still later the milk diet came into general use in the French naval hospitals for the chronic fluxes of Cochin China. Favorable accounts of its success in the hospital at Brest have been given by E. BARRET—*De l'emploi du lait dans le traitement de la dysenterie chronique*, same Jour., T. XX, 1873, p. 370; and H. BIZIEN—*Contribution a l'étude du traitement de la dysentérie chronique coloniale par la diète lactée*, Paris Thesis, No. 306, 1873. For the hospital at Rochefort by L. C. CLAVEL—*De la dysentérie chronique des pays chauds et de leur traitement par la diète lactée*, Paris Thesis, No. 233, 1873; and for that at Cherbourg by C. M. J. HODOUL—*De la médication lactée dans la dysentérie et la diarrhée chroniques*, Paris Thesis, No. 302, 1873.

even in the early stages of acute dysentery. In the advanced stages of the diphtheritic form of the disease, when it becomes necessary to support the strength of the patient, it can frequently be given with advantage in the form of milk punch made with whiskey or brandy, and the same preparation is exceedingly serviceable in debilitated chronic cases. In ordinary acute diarrhœa and in the chronic fluxes, milk given by itself, especially if boiled, often proves an easily digestible and nourishing article of food, and it may frequently be beneficially combined with the farinaceous articles of diet, rendering them both more agreeable and more nourishing. Prudence in its use is, however, required, and it should not be urged upon patients to whom it is distasteful, or with whose digestion it evidently disagrees.

The use of *whey* continued to find supporters long after doubts began to be entertained with regard to milk. Sydenham employed it freely; Baglivi praised it in extravagant terms; it was commended by Hoffmann, Degner and Zimmermann.* In more modern times it has been extensively prescribed, with the addition of sherry or some similar wine, under the name of wine whey. The ancients ascribed to it laxative and detergent properties,† and employed it freely both by the mouth and as an enema. Savignac,‡ who objects to its habitual use in the alimentation of dysenterics, admits its laxative virtues, and favors its employment as an adjuvant with manna or tamarinds. I do not attach much importance to its use for this or any other purpose, and think there is no cause to regret the neglect into which it has recently fallen.

The farinaceous articles of food have always held a prominent place in the alimentation of diarrhœa and dysentery. The Greek physicians employed bread of various kinds soaked in water or boiled with milk, and a great variety of gruels, prepared with or without milk, from barley, rice, wheat flour, oatmeal, starch and other farinaceous articles still in use, as well as some that have become obsolete.§ To these, commerce with the East Indies has added sago, and America has contributed tapioca and potatoes.‖ It was long considered advantageous to cook astringent herbs or fruits with these preparations;¶ a pernicious practice which has fortunately been abandoned. With this change the farinaceous preparations have continued to enjoy a widespread popularity until the present time.

---

* Sydenham—*Med. Obs.*, Sect. IV, Cap. 3, Vol. I, p. 174, Transl. cited p. 407, *supra*. Baglivi—*Praxeos Med.*, Lib. I, Cap. 9, Lyons, 1699, p. 78—declared that he often cured dysentery with whey alone, given both internally and in clysters. Hoffmann—T. III, p. 158, *op. cit.*, p. 647, *supra*. Degner—Cap. III, § 77, p. 192, *op. cit.*, p. 625, *supra*—not merely commended the use of whey, by which he said he had obtained the best results, but preferred to use it in a subacid condition, and even sometimes substituted buttermilk, or even milk itself a little sour—p. 310—regarding the acidity of importance in neutralizing the alkaline bile which played so great a part in his conception of the disease. Zimmermann—Cap. IV, S. 72, *op. cit.*, p. 648, *supra*—"allowed whey in great plenty, and preferred it to water" as a drink.

† See especially the account of the virtues and medical properties of whey given by Galen—*De Simpl. Med. Temp. ac Fac.*, Lib. X, Cap. 2, § 8, [Ed. Kühn, XII, p. 266.]

‡ Savignac—p. 466, *op. cit.*, p. 620, *supra:* "Ce n'est pas, au surplus, l'une de mes boissons favorites, et je le réserverais volontiers pour servir seulement de véhicule adjuvant à certains purgatifs."

§ The properties of these farinaceous articles have been discussed at length by Galen in the first book of his treatise *De Aliment. Facultatibus*, [Ed. Kühn, VI, p. 453 *et seq.*] In Cap. 17, p. 525, he lauds the virtues of rice in checking alvine fluxes. Twice-baked bread and flour boiled with milk are mentioned by Cælius Aurelianus—*Morb. Chron.*, Lib. IV, Cap. 6, p. 526, *op. cit.*, p. 664, *supra*—as having been used for the diet of dysenteries by Praxagoras. Directions for the use of farinaceous articles of various kinds, with or without milk or eggs, will be found in Ætius—Tetrab. III, Serm. I, Cap. 45, p. 604, Ed. cited p. 644, *supra;* Alexander of Tralles—pp. 433 and 438, *op. cit.*, p. 624, *supra;* and very many of the subsequent writers on dysentery.

‖ Sago is praised by Degner—Cap. III, note to § 70, p. 182, *op. cit.*, p. 625, *supra*—who also comments favorably on the use of potatoes, saying that he allowed his patients to indulge in them throughout the whole period of the Nimeguen epidemic, and saw no harm result from their use. He describes them as, "tubera illa Americana, quæ a quibusdam Patatos et Patatoes, ab aliis Papas Americanum ab aliis solanum tuberosum esculentum vocantur." Tapioca, so far as I can learn, was first recommended as an article of diet in dysentery by Piso—*De Med. Brasiliensi*, Leyden, 1648, Lib. II, Cap. XIV, p. 30—who extolled it above all similar articles, and ascribed to it wonderful refrigerating and healing virtues.

¶ This was practiced by the Greek physicians, and Celsus—Lib. IV, Cap. 15—advised that the food and drink in dysentery should consist of those things that bind the bowels gently; but no one has more fully insisted upon it, or carried the plan of admixing such astringents to a greater extreme, than Fab. Hildanus—Cap. 7, p. 676 *et seq.*, *op. cit.*, p. 644, *supra*—who mixed astringents with soups and broths as well as with the farinaceous foods. Traces of the practice will be found in the writings of Hoffmann—T. III, p. 156, *op. cit.*, p. 647, *supra*. Degner appears to have been the first to abandon this vicious custom, and recommends gruels of barley, oatmeal, millet and rice, prepared with milk, as well as various gelatinous broths, to be employed without any astringent mixture—p. 188, *op. cit., supra.*

Savignac and Barrallier have discountenanced their use, giving the preference to nitrogenous food as better adapted to gastric digestion; if farinaceous articles are used at all, Savignac prefers such preparations as vermicelli, semolino, etc., which are rich in gluten, rather than ordinary bread, or, still worse, the preparations consisting almost exclusively of starch.* These objections are not without force, but it is possible to go too far in this direction. Conditions certainly occur in the early stages of acute dysentery which, so long as they exist, render the administration of any considerable quantity of starchy food injudicious. When the anorexia is extreme, and almost anything introduced into the stomach excites vomiting, it is, of course, worse than useless to attempt to force such food upon the patient. Moreover, as long as the mouth is quite dry and its scanty secretions highly acid, the saliva is incapable of transforming starch, and most probably the pancreatic and intestinal juices have equally lost that power.† Under such circumstances the quantity of starchy food that can be digested is at best extremely small, and the remainder, fermenting in the alimentary canal, passes out with the stools as the so-called frogs'-spawn or sago-grain bodies,‡ after having doubtless exercised an injurious influence on the diseased mucous membrane. Even after the mouth becomes moist, and the patient begins to have some appetite, the quantity of starchy food that can be digested remains small, as shown by its appearance in the stools whenever any considerable quantity of it is taken.

Farinaceous food ought not then to be given in the early stages of acute dysentery, and even later in the disease not in excessive quantities, nor to the exclusion of nitrogenous food; but administered in moderate quantities and in connection with other diet, there seems to be no reasonable objection to it after the patient begins to have some appetite; and it has a still wider range of usefulness in non-febrile acute diarrhœa and in the chronic fluxes. Under such circumstances, too, custards composed of starchy preparations boiled with milk and eggs, sweetened and agreeably flavored, are often relished by the patients, and in moderate quantities nothing but benefit is to be anticipated from their use. Among the farinaceous articles of diet rice has probably enjoyed the highest reputation. The opinion of Galen,§ that it exercises a restraining influence upon the bowels, has been accepted unchallenged by the majority of physicians. Boiled with milk it is still generally believed to be possessed of special anti-diarrhœic virtues, and the gruels and custards prepared from rice flour are not only supposed to share these properties, but on account of their delicate flavor are very acceptable to the patients. This high reputation appears to be based upon tradition rather than accurate comparison with other farinaceous food, and doubtless the good qualities of rice have been exaggerated, but I cannot agree with Savignac,‖ who has carried his prejudices against it to the extent of proscribing its use.

Any of these preparations, if given at all, may safely be sweetened to taste. The older physicians had a prejudice against the use of sugar in dysentery, because they supposed it to be readily converted into bile, and loaf-sugar was regarded as particularly objectionable, because the lime used in refining it was believed to confer a certain degree of acrimony upon it.¶ This prejudice has long been deservedly abandoned. Yet it should not be

* SAVIGNAC—p. 455, *op. cit.*, p. 620, *supra*; BARRALLIER—p. 785, *op. cit.*, p. 03, *supra*.

† Compare UFFELMANN—*op. cit.*, p. 388, *supra*. ‡ See p. 375, *supra*. § See note §, p. 666, *supra*.

‖ SAVIGNAC—*loc. cit.*—declares that rice, "which an absurd prejudice regards as anti-diarrhœic, although it gives indigestions or diarrhœa to many persons," is one "of the aliments which are least suited to dysenterics, above all when it is mingled with milk." BARRALLIER—*loc. cit.*—directs that the physician "should proscribe farinaceous food, and above all rice.'

¶ Compare FAB. HILDANUS—Cap. 7, p. 680, *op. cit.*, p. 644, *supra*. The opinion that sugar turns into bile is based upon a similar utterance of GALEN with regard to honey—*De Aliment. Fac.*, Lib. III, Cap. 39, [Ed. Kühn, VI, p. 742.] See also SENNERTUS—T. III, p. 184, *op. cit.*, p. 645, *supra*—who clearly expresses the same views.

forgotten that in the same conditions of digestive debility in which the starches escape transformation, the power of transforming cane into grape sugar is also diminished or lost, and that the temperature of the body is favorable to its fermentation. Under such circumstances it should be cautiously used or altogether avoided, and even later in the disease it is well to be moderate in its employment. In the conditions of extreme apepsia just referred to, it has been proposed to administer a solution of grape sugar, as affording the form of nutriment produced in normal digestion from the starchy and saccharine articles of diet without taxing the enfeebled digestive organs. Doubtless there may be conditions in which this solution might be advantageously resorted to, though experience is lacking to define the limits of its usefulness; but it is evident that if too concentrated, or administered in excessive quantities, so much of the sugar as is not absorbed would be especially prone to undergo fermentative changes, the products of which could not but exercise a mischievous influence upon the diseased mucous membrane.*

The *fats* should, as a rule, be avoided in the alimentation of acute dysentery, and should only be allowed with moderation in non-febrile diarrhœa or the chronic fluxes.† The ancient practice of administering oily substances for their supposed detergent properties, or with the expectation of sheathing the mucous membrane and protecting it against the excoriating action of acrid humors, has long since lost credit, although the use of castor oil as a purgative continues to find favor among some modern physicians.‡ As aliment in acute dysentery the fats are objectionable, because they are not easily digested and because they readily undergo decompositions by which the fat acids are set free in the alimentary canal, where they cannot but exert an unfavorable influence. Moreover, the diminution or cessation of the secretion of bile during the acute stages of the disease is, as Uffelmann§ has pointed out, an additional reason for the difficulty with which the fats are digested at this period, and it is well to abstain from them until the hepatic secretion is restored.

Nitrogenous food.—All kinds of fish and flesh in the solid form were regarded by the Greek physicians as unsuitable diet for patients laboring under acute dysentery; yet when the disease became chronic, as well as during convalescence, they allowed with caution the use of broth.‖ Fish that live among the rocks were supposed to be especially suitable, and the flesh of wild birds and quadrupeds to be preferable to that of domesticated animals.¶ Chicken broth and broth made from partridges were allowed, at least in malignant cases,

* UFFELMANN—S. 249, *op. cit.*, p. 388, *supra*—who recommends for this purpose a solution of grape sugar in water with the addition of "a little good red wine," strongly insists upon the precautions indicated in the text.

† ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 442, Ed. cited p. 624, *supra*—declared, in speaking of the use of flesh in dysentery, that "nothing fat, or difficult of digestion ought to be given." This objection to fat, constantly repeated by subsequent writers, still prevails among physicians. Thus SAVIGNAC—pp. 455-6, *op. cit.*, p. 620, *supra*—not only insists that the meat given to dysenterics shall be devoid of fat, and that the fat shall be carefully skimmed from the broths and soups administered, but would limit the use of eggs on account of the fat contained in the yolk.

‡ The use of fatty substances in dysentery to cleanse or disembarrass the bowels of their acrid contents is directed in the Hippocratic treatise *De Affectionibus*, § 23, [Ed. Littré, VI, p. 235.] On account of their supposed sheathing properties the Greek physicians administered the fats by injection even more frequently than by the mouth, as will be seen when enemata are under discussion. Without multiplying passages to illustrate their internal use, I may refer to ÆTIUS—Tetrab. III, Serm. I, Cap. 45, p. 604, Ed. cited p. 644, *supra*—who advises that a little oil, or still better, fresh goose fat or chicken fat be added to the farinaceous paps given to dysenterics. According to FAB. HILDANUS—Cap. 9, p. 684, *op. cit.*, p. 644, *supra*—fatty broths, butter, olive oil or oil of sweet almonds may be advantageously given to relieve the pain of dysentery; and SENNERTUS—T. III, p. 184, *op. cit.*, p. 645, *supra*—declared that fat added to broth made from the flesh of castrated animals greatly moderates the pains of the disease and heals the ulcers of the intestines. With regard to the use of castor oil, I shall have something to say in connection with the subject of purgatives; meanwhile I note that SAVIGNAC, who so strongly objects to any fatty substances being given as food to a dysenteric—see last note—declares that castor oil is the purgative which he most willingly employs in dysentery—p. 363, *op. cit.*

§ UFFELMANN—S. 242, *op. cit.*, p. 388, *supra*. For a brief account of the case on which he bases this suggestion, see note †, p. 632, *supra*.

‖ ÆTIUS—Tetrab. III, Serm. 1, Cap. 45, p. 605, Ed. cited p. 644, *supra:* "Carnes autem dysentericis non valde commodæ existunt, dandæ tamen eis qui diuturno malo vexantur." ALEXANDER OF TRALLES—*loc. cit.*, note †, *supra*—explains that they are objectionable because they nourish much and are slowly digested.

¶ Compare the lists of fish and flesh given in connection with the passages cited in the last note. The rock fish (ἰχθύες πετραῖοι) are mentioned already in the Hippocratic account of the dysentery of the son of Eratolaus—*Epidem.*, VII, [Ed. Littré, V, p. 373;] and according to CÆLIUS AURELIANUS—*Morb. Chron.*, Lib. IV. Cap. 6, p. 527, Ed. cited p. 526, *supra*—PRAXAGORAS specified them (pisces saxatiles) among the articles of diet which may be allowed to dysenterics.

though they seem to have been prescribed with some hesitation.* When subsequently broths, soups and gelatinous preparations, obtained by the prolonged boiling of flesh, began to enjoy popularity as a means of supporting the failing strength in all severe cases of the disease, it was thought necessary to add astringent medicaments lest they should increase the flux. I find this practice commended as late as in the writings of Hoffmann.†

In modern times various liquid preparations made from flesh have been extensively employed to support the strength of patients laboring under acute dysentery. Indeed, some physicians, reasoning from our recently acquired knowledge of the physiology of the digestive processes and of the modifications they undergo in dysentery, have been led to recommend that the diet should be confined as much as possible to nitrogenous articles. Savignac‡ especially has insisted upon this view, alleging that the digestion of food of this kind being effected chiefly in the stomach by the gastric juice, the diseased intestines are less taxed than by the use of food which is chiefly digested in the intestinal canal. But it is quite possible to go too far in this direction. On the one hand, it should be remembered that in normal digestion both the pancreatic and intestinal juices continue the work begun in the stomach of transforming the nitrogenous elements of the food into soluble peptones; on the other hand, at the beginning of acute dysentery the functions of the stomach are always impaired to an extent proportional to the severity of the disease, while at a later period various degrees of gastric catarrh are, as has been shown in connection with the morbid anatomy, of frequent occurrence.§ In the almost complete apepsia of the early stages of acute dysentery it is worse than useless to attempt to introduce more nitrogenous matter into the alimentary canal than can possibly be digested; and later in the disease, when gastric digestion again revives, the power of digesting starchy food is usually restored to a somewhat corresponding degree.

But while exclusive views of this character are open to criticism, it would be a great error to underestimate the importance of supplying nitrogenous food in an easily digested

* I find in ÆTIUS—Tetrab. III, Serm. 1, Cap. 45, p. 608, Ed. cited p. 644, *supra*—broth made from chickens and partridges (jusculа gallinarum et perdicum) declared to be excellent for those cancerous and malignant cases, (quæ cacoëthe Græci appellant,) which although they are generally incurable, nevertheless ought not to be left without succor. Here also I find a broth made by boiling chickens or partridges in barley or rice water until they fall to pieces, and astringent herbs added, commended for the diet of those whose dysentery results from poisonous drugs. ALEXANDER OF TRALLES—Lib. VIII, Cap. 3, p. 405, Ed. cited p. 624, *supra*—commends chicken broth in the alimentation of hepatic dysentery, but he cautions against using it to excess, especially if it is fatty or contains condiments. He also mentions—Cap. 8, p. 442—that some persons have recommended calves' feet boiled down in ptisan to a thick jelly in the alimentation of ulcerative dysentery, but remarks that it should only be administered if the digestive powers are good, for it perturbs a weak stomach and makes the flux worse than before. It would appear from a passage in PAULUS ÆGINETA—T. III, p. 126, Transl. cited p. 624, *supra*—that broth made "from an old cock" was regarded as laxative; if made from a hen it was supposed to possess astringent properties. GALEN—*De Simpl. Med. Temp. ac Fac.*, Lib. III, Cap. 15, [Ed. Kühn, XI, p. 576,]—had previously declared that the broth of old cocks was laxative, while their flesh was astringent. I find also in AVICENNA—Lib. III, Fen 16, Tract. 1, Cap. 4, p. 818, Ed. cited p. 632, *supra*—a preparation recommended for the diet of dysenteries, made by boiling down flesh (*e. g.*, of young chickens) with rice and millet, straining it, concentrating the solution over the fire till it acquires a gelatinous consistence and adding astringent herbs.

† NICOLAUS PISO—Lib. III, Cap. 15, p. 274, *op. cit.*, p. 665, *supra*—permitted the gruels of rice, &c., administered to dysenteries to be prepared with the broth of a hen or young chickens, instead of with milk. A better appreciation of the value of this kind of food will be found in the treatise of FAB. HILDANUS—Cap. 7, p. 677, *op. cit.*, p. 644, *supra:* "In case the strength fails, consommé and other restoratives (may I thus translate consummata et restaurantia?) made of capons, veal and mutton, are highly advantageous and very nutritious. The flesh is boiled in water until it is wholly separated from the bone, and dissolved into particles, then it is strained through a linen cloth, and the fat skimmed off." He adds that when cold this gelatinizes, and that it should be warmed for administration, and three or four spoonfuls given every four hours. But he is not content with the preparation made in this simple way, and must needs spoil it by the addition while cooking of bistort, tormentil, prepared coral, hartshorn and what not. He praises highly a restorative invented by QUERCETANUS, made by mincing a capon with one or two partridges and some mutton or veal, macerating twelve hours in white wine, then introducing the whole into a glass bottle, adding cinnamon, nutmeg, prepared pearls, coral, astringent flowers, &c., and, closing the mouth of the bottle, introducing it into a vessel full of water and boiling for seven or eight hours. The juice was then strained through a linen cloth, the fat skimmed off with a silver spoon and the resulting extract used as the simple preparation described above. Of course this precious extract (pretiosum jusculum) is too costly for the poor, who can, however, cut up a capon with some mutton, put it with a little cinnamon into a glass bottle and boil it, which will yield an extract quite good enough for them. HILDANUS also mentions gelatin prepared by boiling calves' feet along with the meats named above, as useful both in restoring the strength and constringing the flux; of course he must needs add to this, also, bistort, tormentil, hartshorn, &c. SENNERTUS—T. III, p. 184, *op. cit.*, p. 645, *supra*—directs that broths shall not be given unless they are endowed with astringent properties by the addition of suitable medicaments. They are then well fitted to support the failing strength. HOFFMANN—T. III, p. 156, *op. cit.*, p. 647, *supra*—also advises the addition of astringents to the broths administered to dysenterics.

‡ SAVIGNAC—p. 455, *op. cit.*, p. 620, *supra*. This view followed by BARRALLIER—p. 785, *op. cit.*, p. 603, *supra*.

§ See pp. 314, 456, 525 and 528, *supra*.

form so soon after the onset of an attack of acute dysentery as the patient can manage it. The idea, so strenuously insisted upon by Broussais* and his followers, that the inflammatory process in the intestine can be subdued by an antiphlogistic regimen is altogether erroneous. Unable to digest in the early stages of the disease, the patient soon falls into a condition in which lack of adequate nourishment aggravates, instead of subduing, the local disease, and a sustaining treatment becomes as indispensable as in other inflammatory processes.† Particularly in diphtheritic dysentery after sloughing has commenced are supporting measures urgently demanded.

Broths and soups, especially those made from chicken or beef, are suitable for administration as early in the course of an acute dysentery as the stomach will retain them. Chicken broth is perhaps earliest borne; that made from beef is the most nutritious; mutton broth holds an intermediate place in this respect, but its flavor is less generally acceptable.‡ When either of these broths is first administered the fat should be carefully removed by skimming; it should not be too highly seasoned, nor should it be thickened with flour. Later in the disease a moderate quantity of flour-thickening is not objectionable, and in chronic cases it is not necessary to skim off all the fat if the patient relishes the soup better with a little remaining. The question of the addition of vegetables will be referred to further on. Properly made beef broth or soup especially is quite nourishing, if the patient be able to retain and digest a sufficient quantity.§ In consequence of the practical difficulties in these two directions various endeavors have been made both to obtain greater concentration and to facilitate digestion.

Endeavors of the first kind have led to the invention of the several forms of *beef tea* and *beef essence*,‖ for the extemporaneous preparation of which various formulæ have been

---

* BROUSSAIS—T. III, p. 207 *et seq.*, *op. cit.*, p. 643, *supra.*

† HASPEL—T. II, p. 142, *op. cit.*, p. 621, *supra*—has drawn a pitiful picture of the consequences of the antiphlogistic regimen as practiced by himself in the dysentery of Algeria on his first arrival in that country: "I kept my patients on a severe regimen, trying their digestive powers very gradually, (tâtonnant peu à peu les forces digestives,) always trembling lest premature alimentation should augment the disease. I prolonged their stay in hospital, and when at last, after a thousand accidents, they reached a tardy convalescence, they were œdematous, debilitated, cachectic, (cacochymes,) emaciated and liable to frequent relapses which often proved fatal."

‡ Of these SAVIGNAC—p. 456, *op. cit.*, p. 620, *supra*—gives the preference to beef, which is certainly the most nourishing. Compare the account of the various forms of broth (bouillon) by FONSSAGRIVES—*Hygiène Alimentaire des Malades*, &c., 2me Éd., Paris, 1867, p. 126 *et seq.* He remarks: "Beef broth is the only one to which recourse is had when it is wished to give to the sick a reparative aliment; the broths of the white meats, on the contrary, are preferable when it is proposed to unite the benefits of a light aliment with those of a diluent and slightly laxative drink."

§ MAGENDIE—*Rapport de la commission dite de la gélatine*, Comptes Rendus, T. XIII, A, 1841, p. 261—found that the bouillon used at the St. Louis hospital in Paris contained only from 11.8 to 17.1 grammes of dry residue per litre, of which from 4.76 to 9.86 grammes were saline matter. Even the carefully prepared bouillon of the Compagnie hollandaise—p. 263—only contained from 21.56 to 25.5 grammes of dry residue, of which from 7.28 to 9.98 were composed of salts. It cannot then be expected that any ordinary broth will contain more than 2 per cent. of organic matter. See, also, on the subject of these preparations E. SOUBEIRAN—Art. *Bouillon*, in Dict. de Méd., 2me Éd., T. V, Paris, 1833, p. 514; J. PEREIRA—*A Treatise on Food and Diet.* Amer. reprint, New York, 1843, p. 196; and Z. ROUSSIN—Art. *Bouillons*, in Nouv. Dict. de Méd. et de Chir., Pratiques, T. V, Paris, 1866, p. 442. The last cited author insists especially upon the precautions, first pointed out by CHEVREUL in a report to the Academy of Sciences, Jour. de Pharmacie, T. XXI, 1835, p. 237, that to make good broth the meat should be put into cold water and gradually raised to the boiling point, at which it is to be maintained for some time. While, on the other hand, if the meat when boiled is to be eaten instead of the soup, it should be introduced at once into water already boiling. According to FONSSAGRIVES—p. 119, *op. cit.*, *supra*—550 grammes of beef should be allowed to each litre of water to make a really good broth, which will have a specific gravity of about 1015. F. W. PAVY—*A Treatise on Food and Dietetics*, London, 1874, p. 474—remarks on the preparations of broths and soups: "To accomplish what is aimed at in the most complete manner the meat should be chopped or broken into fine pieces, and placed in cold water. After being allowed to macerate a short time, for the soluble constituents to become dissolved out, it is gradually heated to a point which should vary according to the product required. In the case of broths and beef tea, which properly contain only the flavoring principle of meat—*osmazome*—and the soluble constituents, with finely coagulated albuminous matter, all that is required is to produce gentle simmering, and this should be kept up for about half an hour. In the case of soups a prolonged gentle boiling is required, in order that the gelatine may be extracted, this being the principle which gives to good soup its property of solidifying on cooling. Bones require boiling a longer time than meat. The chief principle they yield is gelatine, and its extraction is greatly facilitated by the bones being broken into fine fragments previous to being used."

‖ Beef tea is named already among the aliments suitable for dysenteries by MACBRIDE (1772)—Part II, Book III, Chap. 3, p. 468, *op. cit.*, p. 664, *supra*. As at present understood, it is simply a strong beef broth so made as to extract as little gelatin as possible from the meat. This precaution was not formerly considered desirable. On the contrary the reader must have observed how carefully prolonged boiling was directed in the receipts for preparing concentrated broths cited from FABRICIUS HILDANUS in note †, last page. In the same spirit UDALRICUS REYDT—*Diss. de jure esculento*, Basel, 1718, p. 9—declared that the gelatinous broths (jusculæ gelatinæ) are deservedly called "jus consumatum." Accordingly, until quite recently, beef tea was boiled for some time, and, I may add, usually made with more water to a given weight of meat than is now thought best. In illustration I may cite the receipt of KITCHINER—*The Invalid's Oracle*, (from the 6th London Ed.,) New York, 1831, p. 80—which directs a pound of lean beef to be cut into thin slices, put into a quart and half a pint of cold water, and gradually warmed until "the scum rises." This is to be removed, the saucepan covered and boiling continued "for about two hours;" after which "skim the fat off, strain it through a sieve or napkin, skim it again, let it stand ten minutes to

published; while under the name of *extract of beef* a variety of manufactured articles, claimed to represent the alimentary principles of meat in a concentrated form, have of late been thrown upon the market.* These latter preparations, which it is asserted have the further advantages for the military medical service of keeping for a considerable time, of being readily transported and of saving the labor of extemporaneous preparation, have been made the subject of numerous investigations, and sharp controversies have arisen as to their mode of action and nutritive value.

Chemical analysis has shown that even extracts prepared after the process devised by Liebig, and these are as a rule the best in the market, contain only from six to ten per cent. of nitrogen, and this chiefly in the form of creatin, creatinin and extractives.† If

settle, and then pour off the clear tea." The receipt given by THACHER—*American Modern Practice*, New Ed., Boston, 1826, p. 777—which has had considerable vogue in America, is made with a pound of beef to the quart of water and boiled twenty minutes. But almost all the modern receipts for the extemporaneous preparation of beef tea are based upon the formula for "flesh broth" (Fleischbrühe) devised by LIEBIG—*Ueber die Bestandtheile der Flüssigkeiten des Fleisches*, Annalen der Chemie und Pharmacie, Bd. LXII, 1847, S. 360—in which equal parts of meat and water are used, and prolonged boiling carefully avoided. He directs a pound of lean beef, free from fat and bone, to be finely hashed and mixed with an equal weight of cold water, then slowly heated and very gradually brought to a boil. After boiling a few minutes only the fluid is to be strained off through a napkin, and by firm squeezing the whole expressed. It may be colored with caramel and flavored with salt and other condiments to taste. LIEBIG declared that thus prepared, the broth contains more nutritive matter than if the boiling be prolonged. Some of the writers who with various modifications have repeated this formula boil about the same time, *e. g.*, FONSSAGRIVES—p. 126, *op. cit.*, *supra*—who recommends two minutes; while others have returned to the old habit of protracting the ebullition, *e. g.*, SAVIGNAC—p. 461, *op. cit.*, p. 620, *supra*—who boils half an hour, and PAVY—p. 511, *op. cit.*, *supra*—who boils an hour. SAVIGNAC—*loc. cit.*—indeed, thinks this broth too strong for many cases, in which twice the quantity of water may be used. A few years after the publication of the paper just cited, LIEBIG—*Eine neue Fleischbrühe für Kranke*, Annalen der Chem. und Pharm., Bd.. XCI, 1854. S. 244—suggested a new form of beef tea, which he called "cold meat extract," (Kaltes Fleischextract,) but which has very generally been spoken of as his "fortifying broth," (bouillon fortifiant.) or as "Liebig beef tea." Half a pound of the flesh of a recently killed ox minced fine is mixed with 1½ pounds of distilled water. To this is added four drops of pure muriatic acid and half a drachm to a drachm of common salt. After standing an hour the mixture is thrown on a hair sieve and the fluid drained off without pressure. The turbid fluid that first passes through is returned to the sieve, and this is repeated until it comes through quite clear; half a pound more of distilled water is then poured on, a little at a time. Altogether about a pound of fluid is thus obtained from half a pound of meat. The fluid has a bloody color which disgusts some patients, but which, as DEBOUT—*Sur la préparation d'un bouillon fortifiant*, Bull. Gén. de Thér. Méd. et Chir., T. XLVII, 1854, p. 572—has suggested, is readily concealed by the addition of a little caramel. According to LIEBIG—*loc. cit.*—this cold extract may be given cold, a cupful at a time. It ought not to be heated, because this precipitates the albuminous matter it contains, and in summer it should be kept in a cold place, and only a little made at a time because it putrefies very readily. Still another mode of preparing beef tea is attributed by THACHER—*loc. cit.*, *supra*—to RUSH: "Cut a pound of beef, first deprived of its fat, into small pieces so as to be put into a quart bottle. The bottle well corked, without the addition of water, should be put into a small pot of cold water, which should be boiled for three or four hours. The liquor should then be poured out of the bottle and made savory with a little salt and any agreeable spice." The authority of RUSH gave this preparation great popularity in Philadelphia, where it was long annually commended by my venerable perceptor, Dr. GEORGE B. WOOD: see his *Treatise on the Practice of Medicine*, 6th Ed., Philadelphia, 1866, Vol. I, p. 395—where he declares that this preparation "in the quantity of from a teaspoonful to a tablespoonful, repeated at intervals of half an hour, an hour, or two hours, aids greatly in the support of the system" in typhoid fever and other low states of disease.

* I will not even attempt to name the various forms of concentrated beef extract with which the market has been flooded. The best are made by the process devised by LIEBIG and described in the first of his papers cited in the last note, S. 360. It is made by a prolonged evaporation over a water bath at a moderate temperature of the flesh broth described in the same essay. Thirty-two pounds of beef thus treated yield a pound of a soft dark-brown mass which LIEBIG called meat extract, (Fleischextract,) and subsequently—*Extractum carnis*, Annalen der Chemie und Pharmacie, Bd. CXXXIII, 1865, S. 125—authorized GIEBERT, who manufactured it on a large scale in Uruguay, to call it "*Liebig's Extractum Carnis.*" According to LIEBIG, half an ounce of this extract, with the addition of a little salt, is sufficient to convert a pound of water into an agreeable and nutritive beef tea. During our civil war a variety of beef extracts were purchased by the Medical Purveying Department of the Army; the total quantity, according to an examination of the accounts of the Purveying Department by Surgeon W. C. SPENCER, U. S. A., amounting to 570,980 pounds. A portion of this supply was quite liquid, and although put up in tin cans a good deal of it soon spoiled, so that it early lost popularity. Most of the more solid extracts subsequently purchased contained a considerable quantity of gelatin, as was ascertained by analyses at the laboratory of the Surgeon General's Office. Beef extract made on LIEBIG'S plan was not, so far as I know, an article of commerce in this country until after the civil war.

† According to LIEBIG—*Ueber den angeblichen Kochsalzgehalt des Extractum Carnis Americanum*, Annalen der Chemie und Pharmacie, Bd. CXL, 1866, S. 249—meat extract prepared by his method ought to contain from 16 to 21 per cent. of water, 18 to 22 of ash and 56 to 66 of extractive soluble in alcohol of 80 per cent. It ought to contain *no* gelatin, which LIEBIG designates the true enemy of good beef extract. KEMMERICH—*Ueber die Wirkungen, den Ernährungswerth und die Verwendung des Fleischextracts*, Deutsche Klinik, Bd. XXII, 1870, S. 152—gives the following analysis of LIEBIG'S extract: Water 16 per cent.. ash 18 to 20.1, extractives, soluble in alcohol of 80 per cent., 81.5, (?,) nitrogen 9.51. PARKES—p. 254, *op. cit.*, p. 599, *supra*—analyzed five samples of LIEBIG'S extract, some of them from Australia and South America. The average amount of water was 16 per cent., of ash 20, of nitrogen 8 per cent., (the lowest being 6.6, the highest 10.14;) he also found a notable quantity of free and combined lactic acid. If with H. LETHEBY—*On Food*, 2d Ed., Amer. reprint, New York, 1872, p. 111—we adopt the conclusions of EDWARD SMITH, "that even in periods of idleness a man's daily food should contain not less than 4,300 grains of carbon, with 200 of nitrogen," it will be seen that it would take a considerable quantity of beef extract to supply the necessary nitrogen, supposing the whole of that contained in the extract could be utilized. With regard to the inorganic salts contained in LIEBIG'S extract, PARKES—*The action of extractum carnis*, Army Med. Dept. Report, Vol. IX, 1867, Appendix, p. 259—estimates the potash salts, chiefly chloride and phosphate, at 66 grains per ounce; this is on the supposition that they amount to "90 per cent. of the soluble salts (which is really too high for the commercial article.)" According to W. BOGOSSLOWSKY—*Phys. Studien über die Wirkung der Fleischbrühe, des Fleischextractes, der Kalisalze und des Kreatinins*. Archiv für Anat. Phys. und Wiss. Med., 1872, S. 351—LIEBIG'S extract contains 22.7 per cent. of ash, of which 21.5 is soluble and 1.1 insoluble. The soluble salts consist almost entirely of phosphate and chloride of potassium. The same investigator found in this extract 2.726 per cent. of creatinin, (mean of 6 analyses, S. 422.) For several analyses of commercial extracts of meat and a brief account of the Russian Tablettes de Bouillon, see LETHEBY—*op. cit.*, *supra*, p. 173 *et seq.* I may mention in this place that the late Dr. B. F. CRAIG, formerly chemist of the Sugeon General's Office at Washington, wrote an ingenious report (Dec. 11, 1869) on the analysis of beef extracts, in which he proposed to determine their comparative value by dialysis. He took the ground that these preparations contain: "Firstly, the real piece of meat, or the soluble matter contained in muscular fibre; and secondly, the products of the transformation of animal tissues by the action of hot water. The first group of substances may in a general way be classified as follows: a. Soluble protein compounds, as albumen and casein. b. Nitrogenous organic bases, creatine, creatinine,

by a stretch of the imagination we could suppose the whole of this nitrogen to represent assimilable nitrogenous matter, the percentage contained in a beef tea made by mixing an ounce of the extract with a pound of water as originally directed by Liebig would be exceedingly small. Accordingly it is by no means wonderful that some have altogether denied that beef extract possesses any nutritive value.* Others, while denying that it can act as ordinary food, have assigned to it properties resembling those of coffee and tea, or at least a gentle stimulating action upon the heart and nervous system; and these effects have been supposed by some to be due to the soluble potash salts contained in the extract; by others to the so-called extractive matters, and particularly to the creatinin.† Yet another view is that, administered in moderate and repeated doses, the extract favors the digestion of other food, whether vegetable or animal, increasing in this way the nutritive value of a small quantity of ordinary food by securing its thorough assimilation. For this reason it is claimed to be especially useful to feeble individuals, convalescents and those suffering from the immediate consequences of grave injuries.‡

and sarcine. e. Nitrogenous organic acids, inosic, inosinic, etc. d. Non-nitrogenous organic acids as lactic and others. e. Inosite and other neutral organic compounds. f. Mineral substances, chiefly chlorides and phosphates." CRAIG attempted to separate these dialyzable substances from the gelatinous matters present by dialysis, and, determining the inorganic salts and water in the usual way, supposed he had thus a fair measure of the really useful part of the extract. He thus obtained from a sample of LIEBIG'S extractum carnis manufactured in South America: Moisture 18.6 per cent., dialyzable matter 54, inorganic salts 22.6. From one manufactured in Texas: Moisture 23.6 per cent., dialyzable matter 52.33, inorganic salts 21.

* Without attempting to give a list of those who have taken this view, I may refer to the experiments of E. KEMMERICH—*Unters. über die phys. Wirkung der Fleischbrühe, des Fleischextracts und der Kalisalze des Fleisches*, Archiv für die Gesammte Physiologie, Jahrg. II, 1869, S. 85—who concludes: "Dass der Liebig'sche Fleischextract für sich allein kein Nahrungsmittel ist." He fed two dogs, 8 weeks old, the one on water alone, the other, besides water, received 5 grammes of LIEBIG'S flesh extract daily. At the end of 5 days the dog fed on the extract had lost more weight than the one fed on water only. The dogs were then fed for 16 days on milk and raw flesh, and when in good condition the experiment was commenced anew. This time the dogs were fed as before, but the experiment was prolonged; on the 12th day the dog fed on flesh extract died, the other, though emaciated and feeble, could still stand and walk, and on receiving good food soon recovered. This result was the more striking, because the heaviest, presumably the strongest of the two pups, had been selected to receive the beef extract. KEMMERICH attempts to explain it by supposing the stimulating action on the heart of the potash salts contained in the flesh extract had rendered the processes of tissue-metamorphosis more active than they would otherwise have been. So, too, HÖRSCHELMANN—*Verhandl. des allg. Vereins St. Petersburger Aerzte*, St. Petersburger Med. Zeitschr., N. F., Bd. I, 1870, S. 369—from experiments on convalescent soldiers, concluded, "das Extract ist als Surrogat für Fleisch *nicht* anzusehen." Still more strongly has a similar opinion been expressed by GUSTAV BUNGE—*Ueber die physiologische Wirkung der Fleischbrühe und der Kalisalze*, Archiv für die Gesammte Physiologie, Jahrg. IV, 1871, S. 277 *et seq.*—who seems to attribute the supposed nourishing action of beef extract merely to its agreeable flavor and the hot water in which it is given, comparing its effects upon the sick to that of a fragrant flower, the sight of Raphael's Madonna or hearing a symphony of Beethoven. So, also, P. MÜLLER—*Extracts of meat considered in a physiological point of view*—Moniteur Scientifique, Sept. 1 and 15, 1871; which I have not seen, and cite The Chemical News, Vol. XXIV, 1871, p. 205—concludes from his researches: "Meat extracts are neither directly nor indirectly food, for they do not contain albuminoid matter, neither do the nitrogenous principles which they contain arrest dis-assimilation."

† That the juices of flesh possessed these stimulating properties seemed to be proven by the experiments of J. RANKE—*Tetanus*, Leipsic, 1865, S. 339 *et seq.* KEMMERICH—S. 49 *et seq., op. cit.*, last note—maintained that these properties were due to the potash salts contained in the extracts of flesh: see also his first paper on this subject—*Unters. über die phys. Wirkung der Fleischbrühe*, Archiv für die Gesammte Physiologie, Jahrg. 1, 1868, S. 120—and his article in the Deutsche Klinik cited in note †, last page. In this latter article I find the following expression—S. 153: "Das Fleischextract ist zunächst durch die Anregung der Herzthätigkeit und die Beschleunigung des Blutkreislaufes ein vorzügliches Belebungs-und Stärkungsmittel, ähnlich wie Kaffee, Thee und die Gruppe der Alcoholica. Es unterscheidet sich aber von ihnen wesentlich durch seinen unmittelbar günstigen Einfluss auf die Ernährungsprocesse des Körpers." MAYER—*De la valeur nutritive et médicale de l'extrait de viande*, Annales de la Soc. de Méd. d' Anvers, An XXXI, 1870, p. 470—from a partial repetition of the experiments of KEMMERICH, was led to adopt his conclusions in this and other particulars; and the observations made by HÖRSCHELMANN—*loc. cit.*, last note—on convalescent soldiers, induced him to accept the same views. On the other hand, W. BOGOSSLOWSKY—S. 403, *op. cit.*, note †, last page—concluded from an elaborate series of experiments that the stimulating action of LIEBIG'S extract is due not merely to the potash salts, but chiefly to the creatinin, of which, as we have seen, he found on an average 2.7 + per cent. But any action resembling that of tea or coffee is strenuously denied by other experimenters, *e. g.*, by BUNGE—S. 282, *op. cit*, last note—who concludes from his investigations: "So muss ich doch die weiter gehende Annahme, welche die Extractivestoffe des Fleisches dem Kaffee, Thee, Alkohol etc. als gleich werthvolles Genussmittel zur Seite stellt, als eine vorläufig noch völlig unbegründete bezeichnen."

‡ Even LIEBIG—*Ueber den Werth des Fleischextractes für Haushaltungen*, Annalen der Chemie und Pharmacie, Bd. CXLVI, 1868, S. 138—appears to claim still more than this, when he remarks that "it may be proved with tolerable certainty that the ingredients of broth which are contained in meat extract increase the nutritive value of bread, so that the two together constitute a more perfect nutriment than bread alone. And that in cases where time for cooking is not allowed, [as often happens with troops in the field,] the meat extract with bread is the only substitute for food we possess, needs no further proof." He goes on to cite certain experiments of PETTENKOFER and VOIT to show that in the case of troops in the field deprived of all other nourishment, meat extract is a most precious means to make hunger less unbearable and to keep the men capable of marching. In these experiments—*Unters. über den Stoffverbrauch des normalen Menschen*, Zeitschr. für Biologie, Bd. II, 1866, S. 478, *et seq.*, Versuch I–III—a robust man received on one occasion for 24 hours, on another for 36, besides water, no other food than a little beef extract and salt: 12.5 grains extract, 15.1 grains salt on the first occasion; 13.8 grains extract, 13.2 grains of salt on the second. LIEBIG correctly cites them as remarking: "Das Befinden während der 36 stündigen Nahrungsentziehung war ein völlig normales und es hätte wohl, nach der Versicherung des Hungernden, ein noch längeres Fasten ertragen werden können." Nevertheless the whole tenor of the essay shows that the writers regarded the subject of these experiments as practically receiving no nourishment; that is, in a condition of "Nahrungsentziehung." KEMMERICH—*loc. cit.*, last note—maintained that the potash salts of the extract not merely acted in a similar way to coffee and tea, but exercised a favorable effect in the nutrition of the body. In favor of this view he brings forward the following experiment—S. 151, *op. cit.*: He fed two young dogs of the same age each with the same insufficient amount of food, to which he added for one dog a quantity (not specified) of the mineral ingredients of flesh extract, for the other a corresponding quantity of common salt. The latter at the end of six weeks was so emaciated and feeble that he seemed about to perish, while the dog which received the extract salts was active and well nourished. He now substituted the extract salts for the common salt in the diet of the other dog, without changing it in any other particular, and it speedily recovered

Not merely has the nutritive value of beef extract been questioned, but it has been declared that in overdoses it exercises a poisonous influence, and that its liberal administration, especially to feeble individuals, is liable to produce injurious effects even when it does not amount to actual poisoning. This view was first advanced by Kemmerich,* as a deduction from his experiments on rabbits. He maintained that the soluble potash salts in the extract are the active agents, and that in small doses they stimulate, while in large quantities they paralyze the action of the heart. Bunge,† on the other hand, having repeated these experiments, came to the conclusion that even in the case of rabbits the poisonous properties of the extract had been very greatly exaggerated, and that it would require a larger quantity than the stomach could possibly retain to produce similar effects on the human subject. Bogosslowsky,‡ who admits the poisonous effects of large doses of the extract on rabbits and its injurious action on man, regards these results as due to the action of the creatinin contained in the extract even more than to the potash salts.

The injurious effects of the administration of too much beef extract to feeble individuals are manifested, according to Kemmerich,§ by palpitations of the heart and diarrhœa. From the same cause Bogosslowsky|| observed symptoms of gastro-intestinal catarrh, a sense of uneasiness and oppression in the gastric region, increased secretion of saliva, thirst, loss of appetite, rumbling in the bowels and diarrhœa, together with debility and more or less headache. According to Parkes,¶ in very large doses the extract, like large quantities of meat, sometimes causes heaviness and torpor. Nor in the use of the commercial extract should the injurious effects be overlooked which are likely to result, if from any cause incipient putrefaction has commenced in it; the diarrhœa often observed to follow its use is perhaps not unfrequently due to this cause. These considerations are sufficient to show how unwise it would be to rely too exclusively upon commercial extract of beef in nourishing dysenteric patients. Where beef tea can conveniently be prepared extemporaneously, I am disposed to give it the preference, but would only use either in addition to other nutritive substances, and not to their exclusion. Chemical analysis, physiological experi-

his health and flesh. MAYER—p. 469, *op. cit.*, last note—claims to have repeated these experiments with identical results, and agrees with KEMMERICH that the addition of meat extract to other albuminous food is especially advantageous to the nutrition of those convalescing from wasting diseases. The experiments of HÖRSCHELMANN—*loc. cit.*, last page—seem to confirm these views, and even to show that a smaller meat ration is sufficient to nourish a person who receives meat extract than is required by one who does not. PARKES—p. 254, *op. cit.*, p. 599, *supra*—remarks of the physiological effects of LIEBIG'S extract: "By some its action has been compared to that of tea and coffee, but there does not appear to be any close parallel. By supplying lactic acid and flavoring matters and potash salts, it must aid nutrition, even if we suppose that the nitrogenous principles are useless, which cannot be considered as yet proved." He adds in a note: "Two gentlemen at my request lived for four days on Liebig's extract and bread. One lost weight, but was otherwise healthy; the other became indisposed and gained weight, as if excretion were interfered with. These symptoms were at once removed by the addition of fats and starches to the same diet." PARKES further declares—*loc. cit.*—that LIEBIG'S extract, mixed with wine, "has been employed with great success in rousing men in collapse from wounds." W. A. HAMMOND—*A Treatise on Hygiene*, Philadelphia, 1863, p. 514—declared, during the progress of the civil war, "the importance of extract of beef to armies can scarcely be overestimated. Hundreds of lives have been saved by it on the battle-fields of the present war." General statements of this kind, however, decide nothing as to the nutritive value of beef extract, for under such circumstances it is almost always administered together with wine or spirits, especially during our war with whiskey, and generally soon followed by other food, so that its real effect could only be conjectured.

* KEMMERICH—Papers cited pp. 671 and 672, *supra*.

† BUNGE—S. 277, *op. cit.*, last page—found that a rabbit weighing a kilogram requires about three grammes of potash salts administered by the stomach to kill it. If the poisoning of larger animals were proportional to their weights, a man weighing 75 kilograms would require 225 grammes of potash salts to produce death by heart paralysis. Now experiment shows that large animals are poisoned by proportionally smaller doses than small ones; yet if we assume 50 grammes only of potash salts to be poisonous to a man, death from this cause is quite impossible, because experience shows that the human stomach at once relieves itself of such a great quantity of these salts by vomiting. I may add that PARKES—*loc. cit.*, *supra*—has singularly misunderstood this passage.

‡ BOGOSSLOWSKY—S. 428, *op. cit.*, p. 671, *supra*—concludes: "Der Tod, nach der Einführung von concentrirter Fleischbrühe bei Kaninchen, ist durch die Herzparalyze bedingt, welche durch die Gesammtwirkung der Kalisalze und des Kreatinins herbeigeführt wird." He tried a number of experiments on medical students, intended to show that the action of the extract on man is largely due to the creatinin. A student who took 10 grammes of the extract experienced next day slight catarrh of the stomach with loss of appetite. A dose of 20 grammes produced still more marked disturbance; 30 grammes still more, and the administration of 40 grammes was followed by headache, thirst, loss of appetite and severe diarrhœa, S. 385 *et seq.*

§ KEMMERICH—Deutsche Klinik, 1870, S. 142, cited p. 671, *supra*. || BOGOSSLOWSKY—S. 389, *op. cit.*, p. 671, *supra*.

¶ PARKES—*loc. cit.*, *supra*. In the article on *The action of extractum carnis*, cited p. 671, *supra*, he remarks also: "There is no doubt that when given to sick, and even to healthy persons in very large quantities, the *extractum carnis* does sometimes produce a degree of malaise and, possibly, feverish symptoms," p. 259.

ments and clinical experience combine to show that neither beef tea nor meat extract is the nutritive equivalent of the quantity of meat from which it is made. It may be conceded that both exert a feeble stimulating action, that they favor to some degree the digestive functions, and that they possess slight nutritive properties; but as yet the more thoroughly each of these effects has been investigated the more trifling it appears to be.

Nor can it be regarded as at all settled that the advice of Liebig was wise when he counseled a mode of preparation by which the gelatinous products of the meat should be excluded. It is true that the report of the so called Gelatin Commission of the French Academy, drawn up by Magendie,* threw grave doubts on the nutritive value of these products; and Vrolik's report of the Commission subsequently appointed by the Netherlands Institute† went still further in this direction. But Boussingault found that when gelatin was administered to ducks a considerable portion was absorbed and only a part found its way into the stools. This result was confirmed by the observations of Frerichs on dogs. Moreover, both he and Bischoff found that the administration of gelatin was followed by a marked increase in the quantity of urea excreted.‡ Carl Voit§ has recently made an elaborate experimental investigation of this subject, from which he concludes that, while it has not been shown that gelatin acts as plastic food in the repair of the tissues, yet on account of the readiness with which it breaks up into urea and other products after it has been absorbed into the circulation, it plays a part not unlike that of the fats and other non-nitrogenous bodies, but in a much higher degree.

Accordingly it is not surprising that so careful a writer as Pavy‖ should declare that, although the precise capacity of gelatin as an agent of nutrition is uncertain, there can be no doubt that it behaves like a protein compound in relation to force-production. In fact the cooks of the present day continue to make consommé from beef, much as was done before the days of the Gelatin Commission, by protracting the boiling until the resulting fluid is quite rich in gelatin. It seems by no means certain that this preparation is not really of greater value in the nourishment of the sick than the forms of beef tea from which all gelatin has been rigorously excluded. Since the publication of the researches of

---

* MAGENDIE—p. 237 *et seq.*, *op. cit.*, p. 670, *supra*. The question this commission undertook to investigate was, "Is it possible economically to extract from bones an aliment which alone or mixed with other substances can take the place of meat?"—p. 239. After a series of researches which lasted nearly ten years the commission concluded—see p. 282—that this question must be answered in the negative; that neither gelatin, albumen nor fibrin, taken alone, nourish animals except for a very limited time and in a very incomplete manner. Nevertheless the commission formally declined to express an opinion as to whether gelatin, when associated with other nutritious substances, has any influence upon the nourishment of man.

† *Extrait du Rapport de la première classe de l'Institut royal des Pays-Bas, sur les qualités nutritives de la gélatine*, traduit et communiqué par M. Vrolik, Comptes Rendus, T. XVIII, 1844, p. 423.

‡ BOUSSINGAULT—*Expériences statiques sur la digestion*, Ann. de Chimie et de Physique, 3me série, T. XVIII, 1846, p. 469 *et seq.*—gave a fasting duck 60 grammes of dry gelatin between 8 A. M., and 1 P. M. At 5 P. M. the duck was killed and the intestinal contents as well as the dejections during the period named analyzed: 27.73 grammes only of gelatin were recovered, showing that 32.27 grammes had been absorbed. In a second experiment, the same quantity having been given to another duck at the same hours, the examination showed the absorption of 38.28 grammes. FRERICHS—Bd. III, Abth. 1, S. 682 *et seq.*, *op. cit.*, p. 375, *supra*—gives a brief account of the previous investigations as to the nutritive value of gelatin, and remarks: "The circumstance that the gelatin ingested is never again excreted as such, speaks against the opinion of the French physiologists, who think to have proven its complete uselessness. It must suffer certain metamorphoses during its stay in the organism which cannot be indifferent for the transformation of the tissues, (Stoffwandel,) and which alone can lead to a conclusion as to its nutritive value. After large doses of gelatin, I constantly saw the urine become highly concentrated; its specific gravity rose from 1018 to 1030–34. I sought for leucin and glucin, but could not discover them. On the other hand, the urea was strikingly increased. Gelatin, therefore, suffers the same transformation as the superfluous proteine substances; it surrenders the greater part of its carbon and hydrogen for the purpose of respiration, while its nitrogen is excreted in the form of urea." BISCHOFF—*Der Harnstoff als Maass des Stoffwechsels*, 1853, S. 70; BISCHOFF u. VOIT—*Die Gesetze d. Ernährung des Fleischfressers*, 1860; I cite these two papers from CARL VOIT—S. 311 u. 312, *op. cit.*, *infra*.

§ CARL VOIT—*Ueber die Bedeutung des Leimes bei der Ernährung*, Zeitschr. für Biologie, Bd. VIII, 1872, S. 297. A careful paper, in which the reader will find a good abstract of the history of this question. The author concludes: "On account of the readiness with which it breaks up, it can decompose instead of the circulating albumen, and thus spares this, and also limits the destructive metamorphosis of the albumen of the tissues. From this point of view it produces results similar to those of the fats or carbo-hydrates, only it acts in a much higher degree, exactly like the peptones, which are incapable of being transformed in the body into albumen again," S. 387.

‖ F. W. PAVY—p. 77 *et seq.*, and p. 288 *et seq.*, *op. cit.*, p. 670, *supra*. The opinion cited in the text will be found on p. 79. So also H. LETHEBY—p. 173, *op. cit.*, p. 671, *supra*—remarks: "Possibly it may serve in the direct nutrition of gelatinous tissue, or, by becoming oxydized, it may develope force; for it appears to be transformed, like albumen and fibrin, into urea, and so leaves the system."

Voit, indeed, Uffelmann* has again revived the use of gelatinous broths in the treatment of dysentery, and asserts that he has derived great advantage from them. I see no reason to doubt the correctness of his observations.

With a view to facilitating the digestion of nitrogenous aliments in conditions of apepsia the administration of *pepsin* has been proposed, and has found extensive use with apparent success in chronic dyspeptic conditions of various kinds. Corvisart has suggested its employment in those diarrhœas which appear to result from defective stomach digestion, and some success in this direction is reported to have been obtained with adults by Ballard, and by Barthez with children.† But the observations of this kind are not as yet sufficiently numerous to determine the real usefulness of pepsin in the treatment of fluxes.‡

It has also been suggested that nitrogenous aliment may be treated, out of the body, with a solution of pepsin and muriatic acid at a suitable temperature, and the *peptones* resulting from this artificial digestion administered as a soluble form of aliment quite ready for absorption.§ Leube, who has given this method some trial, states that the technical difficulties in the way of the successful preparation of peptones for use as food are very great, and that the solution, made in the manner indicated, smells so much like vomit that it is difficult to induce patients to swallow it. He claims, however, to have devised, with

---

* UFFELMANN—S. 245, *op. cit.*, p. 288, *supra*—urges the use of these gelatinous broths (leimhaltige Suppen) on account of their freedom from injurious effects, the readiness with which they are assimilated, and the probability of the correctness of the conclusion of VOIT that they economize the oxidation of the albumen of the blood. He refers also to the successful use of gelatin in the diet of fever patients by H. SENATOR—*Untersuchungen über den Fieberhaften Process und seine Behandlung*, Berlin, 1873, S. 184 *et seq.*—who, likewise incited by the experiments of VOIT, has given gelatin as nourishment in various fevers, typhoid, scarlet fever, measles, &c., sometimes even to the extent of 80 grammes and more a day to an adult, and declares not merely that it was valuable as a nutrient in connection with other aliments, but that so far from producing diarrhœa, or aggravating it, if present, it restrained the bowels.

† LUCIEN CORVISART—*Études sur les aliments et les nutriments; nouvelle méthode pour le traitement des malades dont l'estomac ne digère pas*, read before the Acad. de Méd., Dec. 27, 1853, Archives Gén. de Méd., série V, T. III, 1854, p. 238. In this essay occurs the following passage: "*Diarrhée.* Elle est souvent provoquée par le passage, dans l'intestin, d'aliments non digérés, à cause du défaut de sécrétion. Alors il faut employer ma méthode," p. 240. The method is, of course, to give pepsin. It was at CORVISART'S suggestion that BOUDAULT undertook the manufacture of pepsin preparations, which he described in a *Mémoire sur le principe digestif*, &c., read before the Acad. de Méd., Feb. 14, 1854, Bull. de l'Acad. Imp. de Méd., T. XIX, 1853-4, p. 382. A year later he published a pamphlet on the same subject, of which I have only seen the English translation, viz: *On Pepsine*, translated by W. S. SQUIRE, 3d Ed., London, 1863; appended to which I note a letter from EDWARD BALLARD praising the use of pepsin in cases of diarrhœa and lientery arising from a defective secretion of gastric juice. See also BALLARD'S pamphlet *On artificial digestion*, London, 1857, and the essay of CORVISART—*De l'emploi des poudres nutrimentives (pepsine acidifiée)*. Bull. Gén. de Thérapeutique, T. XLVII, 1854, p. 320. The observations of BARTHEZ will be found in an article entitled *Bons effets de la pepsine dans la diarrhée des jeunes enfants*, same Jour., T. XLIX, 1855, p. 513. A summary account of the early history of the use of the gastric juice in medicine will be found in Lecture 49, On Pepsine, by THOMAS KING CHAMBERS; *The Renewal of Life*, Amer. reprint of 3d London Ed., Philadelphia, 1865, p. 589 *et seq.*; and an account of the introduction of pepsin into therapeutics, by CORVISART, is appended to SQUIRE'S translation of BOUDAULT'S pamphlet cited above.

‡ In our own country a serious obstacle to the employment of this remedy results from the circumstance that so much of the pepsin in the market is quite inert, either on account of defective methods of preparation or the changes this substance is so prone to undergo if kept. Acting Assistant Surgeon W. M. MEW reports that during the last few years he has found most of the samples of pepsin offered for sale to the Purveying Department, and examined in the laboratory of the Surgeon General's Office, to be quite inert. On one occasion thirteen samples were offered, of which but a single one possessed any activity. The method of examination was to attempt with proper precautions the artificial digestion of boiled white of egg with each preparation submitted. A recent article by OSCAR LIEBREICH—*The uses of pepsin in medicine, and its preparation*, The Practitioner, Vol. XVIII, 1877, p. 165—makes a similar statement as to the quality of the commercial pepsin of Europe: "But these preparations are very far from stable or reliable, and however active some of them may be when perfectly fresh, they do not remain active, and a large part of the pepsin powders prescribed are absolutely inert." On this statement the Editor of New Remedies, Vol. VI, 1877, p. 111, comments that "however true Professor Liebreich's remarks may be regarding the quality of preparations offered for sale in the German market, they will not hold good on this side of the water. The dry preparations have, we believe, been the ones most largely employed in this country, [*i. e.*, the United States,] and we are not aware that, after several years of trial, their effects have led to want of confidence among those who are capable of being judges." This extract serves only as an illustration of the loose manner in which opinions as to the therapeutic action of medicinal preparations are sometimes formed in America, for the experiments of MEW, to which I may add the clinical observations of H. C. WOOD—*A Treatise on Therapeutics*, 2d Ed., Philadelphia, 1876, p. 579—show that the opinion of LIEBREICH is fully applicable to the preparations sold under the name of pepsin in the United States. I may add that LIEBREICH has suggested solution in glycerine as the best method for the preservation of pepsin originally good.

§ On the artificial preparations of peptones, whether by means of pepsin or pancreatin and their properties, see the paper of G. MEISSNER—*Unters. über die Verdauung der Eiweisskörper*, Zeitschr. f. Rat. Med., 3te Reihe, Bd. VII, 1859, S. 1 *et seq.*—in an appendix to which the therapeutic use of the peptones, both by the mouth and rectum, is suggested. VOIT und BAUER—*Ueber die Aufsaugung im Dick-und Dünndarme*, Zeitschr. für Biologie, Bd. V, 1869, S. 550—gave the latter suggestion experimental trial, injecting a peptone solution into the rectum of a dog, and observed considerable increase in the urea secretion the following day. The use of peptones by the mouth as a means of supplying nitrogenous nourishment in cases of apepsia is discussed by LEUBE and UFFELMANN—*vide infra*—and as late as December, 1877, I find in the Protokoll of the Vereins der Apotheker Berlins—see the Pharmaceutische Zeitung, Jahrg. XXII, 1877, S. 870—a communication by HOBE, entitled *Ueber Anwendung und Bereitung von Pept. syrupiforma, Pept. syrup. aromat. und reines Pepton nach Dr. Adamkiewicz*, which shows that experiments in this direction are still progressing. The method employed to make pure peptone consisted in acting on washed blood-fibrin by muriatic acid and pepsin, precipitating the parapeptone by sodium carbonate, filtering, and concentrating by evaporation at a temperature not exceeding 70° Cent. It is claimed that 16 grammes of this peptone is equal in nutritive value to 20 grammes of meat. An abstract of this paper will be found in New Remedies, Vol. VII, 1878, p. 46.

the coöperation of J. Rosenthal, a mode of preparing peptones without the use of pepsin by the action of acid on meat in closed vessels at a high temperature, and has thus produced an emulsion, sold in Germany under the name of Leube's meat solution, which is said to be of agreeable taste, great nutritive value and admirably suited to cases of apepsia.* Uffelmann has suggested the use of this preparation in dysentery,† but I am not aware that it has anywhere been sufficiently used to give a fair notion of its utility. The same remark may be applied to the internal administration of *pancreatin*, and of peptones prepared out of the body by the action of this substance.‡ In short, it may be said that the investigations hitherto made in connection with pancreatin, like those relating to pepsin, serve rather to indicate the importance of further studies than to determine either the best methods of manufacture or the precise usefulness of the resulting preparations.

The use of finely hashed *raw meat*, found by Weisse,§ at the Children's Hospital, St. Petersburg, so advantageous in the diarrhœa of recently weaned infants, was extended by Trousseau to the chronic diarrhœa of adults with considerable success.‖ Méran employed it with doubtful results in the latter stages of acute dysentery.¶ Savignac** remarked that, while he had never himself employed this method, he was in the habit of directing

* LEUBE—*Ueber die Therapie der Magenkrankheiten*, No. 62 of the Sammlung Klinischer Vorträge von R. Volkmann, Leipsic, 1873, S. 511. Singularly enough, in the American edition of Ziemssen's Cyclopædia, Vol. VII, New York, 1876, p. 474, it is stated in a "Translator's Note" that this lecture "simply states: this solution is prepared by digesting meat with a strongly acid solution of pepsin in hermetically sealed vessels, at a temperature much higher than that of the human stomach," whereas the point of LEUBE'S method, as explained in the lecture, is that no pepsin is used. I may add that the lecturer cautions the reader against the use of any "Fleischsolutionen" except those prepared by Herr Hofapotheker Dr. Mirus in Jena. These keep admirably, but alas! the lecturer often meets at the bedside badly prepared solutions made by other people!!—S. 513. After this we need not be surprised to learn from LIEBREICH—p. 161, *op. cit.*, last page—that the use of the peptones has "great disadvantages, by reason of the readiness with which they decompose into those very disagreeable substances, leucine and tyrosine." He adds: "It is unnecessary to speak of their very disagreeable physical character; these products of the decomposition of the peptones are incapable of supporting the nutrition of the body; and as the object of the administration of the peptones is to make them readily available for such absorption, the promptitude with which they enter on the stage of decomposition is a very serious drawback. There is also great difficulty in preparing them in a state of purity; and even if this be successfully achieved, I believe it would still be much better to entrust the work of preparing the peptones to the stomach, and aid it in the task, when necessary, by the administration of pepsin."

† UFFELMANN—S. 248, *op. cit.*, p. 338, *supra*—declared that he would give it a trial in the next epidemic of dysentery, though he expressed doubts as to how far it is likely to prove useful; for in the less severe cases the stomach is still able to form peptones, and in those more severe ones in which it cannot, it is probable enough that the power of assimilating the peptones after they are absorbed has also been lost.

‡ The modern therapeutic employment of pancreatin, like that of pepsin, is chiefly due to CORVISART. It is true, as he himself frankly stated—*Sur une fonction peu connue du pancréas; la digestion des aliments azotés*, Gaz. Hebdomadaire de Méd. et de Chir., T. IV, 1857, p. 250—that PURKINJE and PAPPENHEIM—see the note of G. VALENTIN, *Einige Resultate der im Sommer des gegenwärtigen Jahres zu Breslau über künstliche Verdauung angestellten Versuche*, Froriep's Notizen, Bd. L, 1836, S. 211—had long before observed that the pancreas yielded a juice which digested nitrogenous matters, as indeed had previously been indicated by EBERLE; compare F. A. LONGET—*Traité de Physiologie*, 2me Éd., T. I, Paris, 1861, p. 268. But the influence of CORVISART'S paper, just cited, and his subsequent essay—*Fonction digestive énergique du pancréas sur les aliments azotés*, Gaz. Hebd., &c., T. VII, 1860, p. 483 *et seq.*—undoubtedly stimulated modern investigation into this function of the pancreas, and suggested the therapeutic employment of pancreatin, which has come into extensive use. It appears, however, to prove most serviceable when employed to emulsify fatty matters before taking them into the stomach. Against its therapeutic use to assist in the digestion of nitrogenous food may be urged the objection of LIEBREICH—*loc. cit.*, note *, *supra*—that it must, "when administered by the mouth, pass through the stomach, which by its acid secretions modifies or destroys" its efficacy as a ferment. I do not know of any attempt to use therapeutically the peptones prepared out of the body by the action of pancreatin, unless we class under this head the meat-pancreas injections which LEUBE—*Ueber die Ernährung der Kranken von Mastdarm aus*, Deutsches Archiv für Klin. Med., Bd. X, 1872, S. 1 *et seq.*—has recommended for cases in which stomach digestion is impossible.

§ J. F. WEISSE, Director of the Children's Hospital at St. Petersburg—*Von der Diarrhoe entwöhnter Kinder, oder der Diarrhœa ablactatorum und deren Kur durch rohes Fleisch*, Jour. für Kinderkrankheiten, Bd. IV, 1845, S. 99; compare his report thirteen years later on his continued success with this treatment, *Rückblick auf den Gebrauch des rohen Fleisches in der Diarrhœ entwöhnter Kinder*, Vergetragen am 19 Sept. v. J. in der Versammlung der deutschen Naturforscher u. Aerzte in Bonn—same Jour., Bd. XXX, 1858, S. 60.

‖ The plan of WEISSE had been received in France with considerable incredulity. Note the scornful "Réflexions" appended to Art. 3087, *De l'emploi de la viande crue pour combattre la diarrhée chez les enfants récemment sevrés*, Jour. de Méd. et de Chir. Pratiques, T. XVI, 1845, p. 440: "La viande crue est la nourriture de certaines peuplades à demi sauvages; et nous avons vu, lors de l'invasion de 1815, des Cosaques manger avec délices des chairs presque palpitantes, et qui avaient à peine été approchées du feu. Le robuste appétit de ces hommes et leur voracité proverbiale pouvaient s'accommoder d'une semblable nourriture; mais il n'y a nulle ressemblance entre l'état de l'estomac d'un Cosaque bien portant et celui d'un enfant nouvellement sevré, et qui ne peut supporter une alimentation trop substantielle." In spite of this kind of opposition, TROUSSEAU succeeded in introducing the use of raw meat into French therapeutics, and early extended its employment to the case of adults laboring under chronic fluxes. See an article entitled *De l'emploi de la pulpe de viande crue dans le traitement de la diarrhée chronique chez les enfants*, Bull. Gén. de Thér., T. LVI, 1859, p. 449; also T. III, p. 123 *et seq.*, *op. cit.*, p. 664, *supra*. To overcome the disgust of sensitive adults he mixed the finely hashed raw meat with a little conserve of roses and prescribed it under the name of "*conserve de Damas.*"

¶ MÉRAN—Bull. des Séances de la Soc. de Méd. de Bordeaux, Nov. 7, 1859, L'Union Médicale de la Gironde, An IV, 1859, p. 516—administered hashed raw meat, flavored with currant jelly, to a dysenteric patient after the acute accidents of the disease began to diminish and the feebleness became marked. At first it appeared to have a good result, but in a few days the patient began to feel disgust, not on account of the taste, but because it was not digested. Pepsin was then added with temporary advantage, but the patient died. In a second case he was more fortunate, and the patient recovered.

** SAVIGNAC—p. 457, *op. cit.*, p. 620, *supra*. A good account of the raw-meat treatment is given by FONSSAGRIVES—p. 610 *et seq.*, *op. cit.*, p. 618, *supra*. See also R. DRUITT—*On the use of raw meat in diarrhœa and dyspepsia*, Med. Times and Gaz., Vol. II, for 1870, p. 4. BARRALLIER—p. 785, *op. cit.*, p. 603, *supra*—thinks raw meat is advantageous and ought to be used in chronic dysentery, especially during convalescence.

convalescents from chronic dysentery to eat their beefsteaks and cutlets as rare as possible. Undoubtedly the fine hashing of the meat renders it easier to digest, and it is probable that rare or underdone meat is more digestible than that which is thoroughly cooked; whether raw meat has any additional advantages is exceedingly problematical.

Oysters, which were regarded by Galen as exercising a restraining influence upon the bowels, were recommended by Alexander of Tralles* as well suited for the alimentation of patients laboring under rheumatic dysentery. Savignac† praises them highly. He often recommended convalescents from dysentery to visit seaside resorts where oysters abound, and partake of them freely; and found that, besides the nutritive value of this acceptable food, it seemed to aid in reëstablishing the normal functions of the intestine. Weisse‡ found them efficacious in the lientery of adults; eight to a dozen taken twice a day often suffice to cure. The Atlantic coast of the United States is remarkable for the size and fine flavor of its oysters. They have been extensively prescribed by our physicians, and during the civil war were purchased in considerable quantities, with the hospital fund of many of the general hospitals, for the use of patients laboring under fluxes. They are to be regarded as highly nutritious, very readily digestible food, and may be used raw, stewed, roasted or steamed, but should not be broiled or fried for patients laboring under fluxes.§ They may be given in acute cases after the first violence of the disease is passed, but are especially suited to convalescents and those who suffer from chronic fluxes. Savignac has correctly stated that in certain cases they disagree and appear to aggravate the flux. This is, however, seldom the case if they are perfectly fresh; if stale they are capable of provoking intestinal disturbance even in healthy subjects.

Eggs have long enjoyed a deserved reputation in the alimentation of dysenterics. Cooked in various ways they were employed for this purpose by the Greek physicians.‖ The use of egg-albumen as a drink has already been discussed.¶ The whole egg may often be used raw as food; the white and yolk being beaten up separately and afterwards mixed with the addition of a little sugar and Sherry wine. Eggs may frequently also be advantageously added to the farinaceous preparations, and with milk and brandy, in the form of milk punch, constitute a concentrated form of nourishment which is often useful in the prostration or collapse of diphtheritic cases. Poached or soft-boiled eggs and light omelets are suitable for convalescents and for chronic cases. In not a few cases, however, eggs disagree, as indicated by uneasy feelings in the stomach and eructations impregnated with sulphuretted hydrogen. On this account they have acquired the reputation of being bilious, and therefore unsuitable for dysenterics. Degner** was quite right in ridiculing

* GALEN—*De Simpl. Med. Temp. ac Fac.*, Lib. III, Cap. 15, [Ed. Kühn, XI, p. 576,]—asserts the juice of the oyster to exercise a relaxing effect, while the flesh restrains the belly. In *De Aliment. Fac.*, Lib. III, Cap. 33, [*Id.*, VI, p. 734,] he remarks that the flesh of oysters does not easily corrupt in the bowels, and therefore is often useful for those in whom corruption of the food is likely to occur, on account of disease of the liver or bowels. ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 441, Ed. cited p. 624, *supra*—advised the use of oysters in rheumatic dysentery. He recommended that they should be roasted in their shells, saying that they assist digestion and restrain the belly.

† SAVIGNAC—p. 460, *op. cit.*, p. 620, *supra*. ‡ WEISSE—S. 64, second paper cited note §, last page.

§ For this purpose if the oysters are stewed it is best to thicken the juice with a little flour, bring it to a boil, drop in the oysters and take them off the fire at once; their flesh is thus set without being shrunk. This is better than the common practice of stewing them in milk. Prolonged stewing makes them tough and more difficult to digest. Steamed oysters are an American dish; the oysters are cooked in the shell by exposing them to steam for a few minutes; they should be done rare. Broiled and fried oysters are chiefly objectionable on account of the fat employed in these modes of cooking.

‖ Thus, in ÆTIUS—Tetrab. III, Serm. 1, Cap. 45, p. 604, Ed. cited p. 644, *supra*—starch cooked with eggs and milk is advised for the nourishment of dysenterics; also (p. 605) the yolks of eggs roasted with a little vinegar, sumac and oil. ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 442, Ed. cited p. 624, *supra*—writes, in connection with the alimentation of rheumatic dysentery: "Thus hens' eggs poached in posca till hardened are advantageous, but their yolks roasted over live coals and rubbed with vinegar and Syrian sumac are more astringent."

¶ See p. 664, *supra*.

** DEGNER—§ 76, p. 192, *op. cit.*, p. 625, *supra*—declares that eggs are not to be dreaded on account of the vain fear of the vulgar that they augment the bile, but rather possess to a high degree demulcent and, at the same time, nutrient properties. SAVIGNAC—p. 456, *op. cit.*, p. 620, *supra*—thinks the usefulness of eggs in dysentery limited on account of the fat contained in their yolks.

this notion; nevertheless it would be bad practice to insist upon the employment of this article of food in cases in which the slightest gastric disturbance follows its use.

The *cooked flesh* of various mammals and birds* is sometimes admissible in the diet of convalescents and of chronic cases. Beef or mutton, roasted or broiled, the former especially should be done rare, chickens and partridges, are among the most suitable for this purpose. Fish as a rule are best avoided, unless particularly craved by the patient, when moderate quantities may be allowed and the effect watched.

Fresh vegetables and fruits.—Vegetables and fruits are not to be blindly avoided by patients suffering with fluxes, as some have directed.† The Greek physicians employed them in moderation even in dysentery, giving preference for the most part to such as were supposed to possess astringent virtues, though Alexander of Tralles boldly recommended the use of laxative fruits in certain cases.‡ This practice had long been undeservedly neglected,§ when in modern times attention was again directed to the use of these articles of diet, partly on account of their laxative effect, but chiefly because of their antiscorbutic properties. Abundant testimony has already been adduced to show the benefit derived from the use of fruit and fresh vegetables in the fluxes of the civil war,‖ and like effects may be anticipated whenever diarrhœa or dysentery is complicated by the scorbutic taint. When the latter condition precedes the flux, which may often be regarded as indirectly its result, the importance of an antiscorbutic regimen is of course apparent. But it should not be forgotten that during the long-protracted course of chronic cases a scorbutic taint, or scurvy itself, may be generated by a diet insufficient in variety, and from which vegetable food is too rigorously excluded. This accident is even more prone to occur in military practice in times of war than in civil life, because a tendency to the scorbutic condition is so frequently present, even when no symptoms express its existence, and a shorter time is therefore required for the development of scorbutic phenomena by unsuitable diet than would be needed under ordinary circumstances.

A suitable admixture of vegetables and fruits is therefore desirable in the alimentation of convalescents and chronic cases even when no scorbutic symptoms have as yet appeared; if these latter are recognizable a decidedly antiscorbutic regimen is imperatively demanded.

---

* The qualities of flesh of various kinds are discussed in the Hippocratic writings; *e. g.*, in *De Affectionibus*, § 52, [Ed. Littré, VI, p. 263;] *De Victus Rat.*, Lib. II, § 46–49, [same Vol., p. 545;] and *De Victus Rat. in Morb. Acut.*, Append., § 18, [same Ed., II, p. 489.] GALEN has treated of the subject at great length; see especially *De Aliment. Fac.*, Lib. III, [Ed. Kühn, VI, p. 660 *et seq.*] The opinions expressed in these works may be compared with interest with those of modern writers; see, for example, FONSSAGRIVES—p. 94 *et seq.*, *op. cit.*, p. 618, *supra*, and PAVY—p. 131 *et seq.*, *op. cit.*, p. 670, *supra*—who has also given—p. 190 *et seq.*—an interesting enumeration of certain exceptional animal foods.

† For example, SAVIGNAC—p. 456, *op. cit.*, p. 620, *supra*—forbids, in the alimentation of dysenterics, the use of "les légumes, les herbages, les fruits crus, les fruits acides surtout."

‡ Thus we have already seen—note §, p. 624, *supra*—that GALEN commended apples, especially sour apples cooked with bread, in cases of diarrhœa and dysentery; elsewhere—*De Rem. Parab.*, Lib. I, Cap. 10, [Ed. Kühn, XIV, p. 370,]—he advises for cœliacs and dysenterics a preparation made by boiling down quinces, pomegranates and sorb-apples. ÆTIUS—Tetrab. III, Serm. 1, Cap. 45, p. 605, Ed. cited p. 644, *supra*—commended the employment in dysentery of a pottage made with dry bread, to which dates, quinces, pears, &c., were sometimes added. He praises lentils cooked with plantain or pomegranates, and flavored with a little vinegar and oil, as possessed of astringent virtues. He remarks that he does not much approve of garden herbs, yet does not prohibit their moderate use, and mentions boiled endives, plantain, heath and cabbage twice boiled in water and afterwards in posca, as suitable. Fruits also should be sparingly employed; if craved, cooked pears, quinces, medlars, pomegranates, &c., may be permitted. ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 439, Ed. cited p. 624, *supra*—advises, in rheumatic dysentery, the use of lentils, and—p. 441—the more astringent garden herbs, especially endives, plantain and black beets. They may be cooked and flavored with vinegar, or, such as are suitable, eaten raw with bread. Cabbage twice cooked possesses drying virtues. The astringent fruits are also commended—p. 443—but sweet fruits should be prohibited, because they generate flatus and readily acidify. Nevertheless, as we have already seen—note §, p. 624, *supra*—he elsewhere commends the use of laxative fruits, such as damsons and grapes in ulcerative dysentery. I may add that, of the Arabian physicians, RHAZES—*Ad Mansor. de Re Med.*, Lib. IX, Cap. 72, Basel, 1544, p. 259—commends for dysenterics a preparation made by boiling pomegranates with raisins in water to which a little vinegar has been added; HALY ABBAS—*Practic.*, Lib. VII, Cap. 22, Lyons, 1523, fol. 246—pears, Pontic apples and medlars; and AVICENNA—*Canon*, Lib. III, Fen 16, Tract. 2, Cap. 7, p. 823, Ed. cited p. 632, *supra*—Indian melons.

§ ACKERMANN—p. 120 *et seq.*, *op. cit.*, p. 620, *supra*—recounted with praise the practice of the ancients in this matter, but his liberal views did not find many followers. Indeed such instances as that related by ROMMEL—note ‡, p. 625, *supra*—and that of the Swiss regiment mentioned by TISSOT—p. 625, *supra*—in which fruit was beneficially used in the treatment of dysentery, occurred quite as often before as immediately after his time.

‖ See p. 626, *supra*, especially the references in note ‡, to which I may add the testimony of W. KEMPSTER—p. 344, *op. cit.*, p. 493, *supra*—who testifies to the speedy diminution of fluxes among our troops during the war whenever they obtained access to green corn in the fields.

Lime or lemon juice mixed with water and sweetened may be advantageously used for this purpose, as was first pointed out by J. Heurnius and his son Otto* in connection with the scorbutic dysentery of the East Indies. It constitutes an agreeable drink which is generally well relished by convalescents and chronic cases, and seldom gripes or disturbs the bowels if sound fruit is used. Orangeade and drinks made from other fruit juices may be employed for the same purpose, but are for the most part more apt to disagree.

In selecting vegetables for the diet of convalescents from dysentery and patients suffering with chronic fluxes, preference should be given to those which are most readily digestible, and care should be taken to reject those which are not perfectly sound and fresh. Potatoes, lauded by Degner† as an innocent food which dysenterics may employ with impunity, are justly regarded as possessed of eminent antiscorbutic virtues, and, as they stand transportation reasonably well, are well adapted for use in military hospitals. These advantages are shared to a certain extent by onions,‡ which, although less nutritious than potatoes, are perhaps more valuable as antiscorbutics; they may be given boiled, or may be sliced and flavored with vinegar and salt. Leeks may be substituted for onions, when they can be obtained fresh, and are relished by the patients. Among the numerous other vegetables that are suitable for this purpose, squashes, pumpkins, carrots, turnips and tomatoes may be particularly mentioned. It may be laid down as a rule, that vegetables containing much cellulose and other indigestible matters which must pass unaltered through the alimentary canal, are to be avoided as much as possible, or, if used, should be boiled until quite tender; with this precaution such vegetables as spinach or even cabbage can often be employed with benefit. Lettuce, if tender and fresh, can often be safely eaten raw as salad, and tomatoes or even potatoes may be employed in the same way.

Any of these vegetables may be advantageously boiled with the soup or beef tea prepared for patients laboring under fluxes. This is particularly desirable if the presence of a scorbutic taint is recognized or suspected. For those suffering with acute dysentery the solid vegetable fragments should be strained out after boiling, and the same may be done in other cases if they appear to disturb the digestive organs; but during convalescence, and the chronic fluxes, this precaution is seldom necessary, and the well boiled vegetable fragments served with the soup are not only innoxious but exercise a salutary influence. In whatever way administered, however, vegetable food should be given in moderate quantities, its effects watched, and the use of any article that appears evidently to disagree with a particular patient should be at once discontinued.

The same precautions should be used in the employment of ripe fruit, which may also be given in moderation to the same class of cases on account of its antiscorbutic virtues. It is also perhaps advantageous because of the laxative effect it induces. This latter affords a probable explanation of the success of the New England physicians who treated acute fluxes with watermelons and peaches,§ though probably the diuretic effect of the melons was also advantageous. Almost any sound ripe fruit may be selected for the purpose in

* J. HEURNIUS, in a note to FERNELIUS—*Universa Medicina, Pathologia*, Lib. VI, Cap. 10, Geneva, 1679, p. 525—remarks: "Those who returned from Java to Amsterdam in the year 1597 relate that a great part of their number perished from dysentery, produced by using spoiled meat, until they found a specific (alexipharmicon) in a mixture of garlic with sugar and lemon-juice." And OTTO HEURNIUS adds in the next note: "Those who sail to the East Indies sometimes fall into dysentery from the use of putrid flesh, for which the most immediate remedy is garlic with sugar and lemon-juice." I may add that HAUFF—S. 438, *op. cit.*, p. 524, *supra*—commends the use in dysentery of acid fruit-juices mixed with water, as lemonade, orangeade, &c., but only on account of their efficiency in allaying thirst.

† DEGNER, see p. 666, *supra*.

‡ Potatoes and onions were the vegetables most liberally supplied to our hospitals during the civil war. They were used with advantage by patients laboring under chronic fluxes and by convalescents; and the only complaints I have heard refer to the difficulty of obtaining them in sufficient quantities.

§ See p. 627, *supra*.

view. Grapes at the Cape of Good Hope, and the Bael fruit in India, have been loudly praised. In our own country blackberries are popularly believed to possess special anti-diarrhœtic properties; but it is doubtful how far this reputation is deserved, and the numerous seeds are not always innoxious.*

VENESECTION.—The older Greek physicians do not appear to have resorted to bleeding in the treatment of the fluxes. Its use for this purpose is not mentioned in the Hippocratic writings, and Galen expressly forbids it.† Among the later Greeks, Ætius and Alexander of Tralles commend the cautious use of this operation in young vigorous subjects laboring under acute dysentery, with the view, as the former explains, of evacuating a portion of the peccant humor, of mitigating the inflammation, and, by revulsion, preventing the blood from accumulating in the intestine. They direct the blood to be drawn from the right arm at the beginning of the disease, and in small quantities only, repeating the abstraction at intervals if necessary.‡ Some of the Arabian physicians§ adopted this practice, which was long very generally inculcated by systematic writers.||

Against even this moderate use of bleeding in dysentery an earnest protest was made by Rondeletus, whose views were more or less closely followed by Felix Plater, Septalius and Willis.¶ On the other hand, Botallus advocated its employment in this disease with the same extravagance with which he recommended its use in other inflammatory and

* CURTIS—*An Account of the Diseases of India, etc.*, Edinburgh, 1807, p. 144—says, speaking of the treatment of dysentery in the Naval Hospital at Madras, 1782-3: "In the secondary stages, we never forbade the use of fruits, especially such as were astringent; as the mango, and guavo or pomegranate; and we always directed a part of the rind to be eaten along with them. They were grateful and useful antiseptics; only, much of the pomegranate rind was too strongly astringent to be used indiscriminately." He adds in a foot note, p. 145: "The author of these observations was reduced to as low a state by bilious flux as ever any European in India. The first turn towards recovery was found at the hospitable tables of Vizagapatam, where all the tropical fruits were in plenty. Nature and appetite prompted strongly, and the fullest indulgence was followed, not only with impunity, but with manifest advantage." The preference for astringent fruits here indicated is quite in accord with the ideas of the ancients. According to Sir JAMES RANALD MARTIN—*Practical observations on the nature and treatment of the diseases of Europeans on their return from tropical climates*, The Lancet, 1853, Vol. II, p. 53: "The subacid fruits have long been used" in the treatment of chronic diarrhœa and dysentery "in the south of Europe, in the East and West Indies, and the grapes of the Cape of Good Hope have during many years been celebrated for their efficacy in the chronic bowel disorders of the numerous invalids who annually resort to that colony from the Indian presidencies." The success of the "Grape Cure" of dysentery is also referred to by W. C. MACLEAN—Vol. I, p. 123, *op. cit.*, p. 657, *supra*—who suggests that it is in the scorbutic form of the disease it has been found so efficacious. He adds a caution with regard to the grape seeds: "I remember the case of a young officer at Secunderabad, who, while convalescing from acute dysentery partook freely of grapes. Shortly after, he was seized with all the symptoms of peritonitis from perforation, and rapidly sunk. After death it was found that a grape stone had become entangled in one of the half cicatrized ulcers in the colon, where it acted like a pea-issue; a minute perforation resulted, causing the death of the patient." In the same passage he speaks very highly of the use of the fresh Bael fruit, but adds: "Bael fruit has often fallen into disrepute as a remedy in dysentery, simply from its indiscriminate use. My conviction is that where there is no scorbutic taint it is without efficacy." On the subject of this article see GRANT—*Note on the preparations and uses of the Bael fruit*, The Indian Annals of Med. Sci., Vol. II, 1854-5, p. 225; and MARTIN—*loc. cit.*, *supra*; see also, by the same author, p. 690, *op. cit.*, p. 621, *supra*. MACLEAN—*loc. cit.*, *supra*—also remarks: "Many of the invalids from India, suffering from chronic dysentery, arrive at Netley in a more or less scorbutic state; all are benefited and some cured, simply by causing them to use whatever fruits are in season."

† GALEN—*Comm. IV in Hippoc. de Acut. Morb. Victu*, § 98, [Ed. Kühn, XV, p. 908:] "If there is a flux of the belly, do not bleed; for if the flux continues after the loss of blood, the strength of the patient will be prostrated." The same view is expressed in *Ad Glauconem de Med. Meth.*, Lib. I, Cap. 15, [Ed. Kühn, XI, p. 43.]

‡ ÆTIUS—Tetrab. III, Serm. I, Cap. 45, p. 606, Ed. cited p. 644, *supra*—explains the action of bloodletting as follows: "Non enim ob multitudinem sanguinis evacuandam sectionem facimus, sed ut materiam quasi per rivos transferamus. Paucus autem sanguis etiam multo tempore emissus, inflammationem mitigat, et sanguinis ad intestina delationem revellit, innatumque calorem sensim refrigerans, somnum magis quam animi deliquium inducit." ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 435, and Cap. 9, p. 457, Ed. cited p. 624, *supra*—commends the same practice, but without expounding the reasons.

§ Thus, for example RHAZES—*Ad Mansor Divisionum*, Lib. I, Cap. 67, p. 390, Ed. cited p. 678, *supra*—counselled bleeding from the arm in bilious dysentery. (fluxus ex copia bilis.)

|| Among these I may mention GORDONIUS—*Lilium Medicinæ*, Venice, 1496, Partic. V, Cap. 14, fol. 161; ALTOMARUS—*Ars Med.*, Cap. 74, Opera, Venice, 1574, fol. 182; HOLLERIUS—*De Morb. Intern.*, Lib. I, Cap. 40, Venice Ed., 1572, fol. 119; FORESTUS—*Obs. et Cur. Med.*, Leyden, 1596, Lib. XXII, Obs. 34, Scholia, p. 375; FAB. HILDANUS—Cap. 8, p. 684, *op. cit.*, p. 644, *supra*; SENNERTUS—p. 131, *op. cit.*, p. 645, *supra*; and RIVERIUS—*Prax. Med.*, (Paris, 1640,) Lib. X, Cap. 6, Opera, Lyons, 1679, p. 302. Most of these writers followed pretty closely the indications laid down by ÆTIUS and ALEXANDER, and bled from the arm; usually the right arm, as directed by ÆTIUS. HOLLERIUS mentions that some physicians prefer to open a vein in the hand as less debilitating, while others bleed at the ankle, which, however, he regards as more debilitating than bleeding from the upper extremity. HILDANUS did not think the quantity taken should ever exceed six or eight ounces.

¶ RONDELETIUS—*Methodus Curandi Morbos*, (1583-5,) Lib. III, Cap. 20, Opera Omnia, Geneva, 1620, p. 457—declared that those who let blood in dysentery do so without judgment or utility, and with great injury to the sick, debilitating the patient without checking the flow of bile or benefiting the ulcers. He explains that these remarks apply to true dysentery only, for a mere hæmorrhage from the intestine (dysenteria cruenta) may sometimes be checked by bleeding. FELIX PLATER—*Praxeos*, Basel, 1736, T. III, Lib. II, Cap. 11, p. 811—regarded bloodletting as of little advantage in this disease; it cannot evacuate from the mesenteric veins, and still further weakens the debilitated powers of life. L. SEPTALIUS—*Animad. et Caut. Med.*, (1629,) Padua, 1652, Lib. VII, § 95-6, p. 226—thought bloodletting seldom required; if used at all, the precepts of ÆTIUS and ALEXANDER should be followed. WILLIS—*Pharm. Rat.*, (1763,) Opera, Geneva, 1680, Sect. 3, Cap. 3, p. 74—declared that bloodletting was not well borne in the London dysentery of 1670.

febrile disorders, and Sydenham* not only bled freely in the acute dysentery of vigorous adults, but claimed that he had drawn blood with advantage even in the case of children, and in chronic dysentery.

The avowed objects of bloodletting were now to cure the intestinal inflammation and to diminish the accompanying fever. For these purposes, with more or less caution as to the amount of blood taken, and more or less restriction of the operation to the so called inflammatory cases, it was employed by the majority of physicians.† Even the great English army surgeons, Pringle and Donald Monro,‡ together with such observers of tropical diseases as Bontius, Hillary and Moseley,§ were swept along with the current of medical opinion. The positive declaration of Degner that, during the Nimeguen epidemic, bloodletting aggravated the symptoms and was often speedily followed by a fatal issue, and the example of Zimmermann, who entirely discarded it during the Swiss epidemic of 1765, although supported by the experience of such excellent practitioners as Rollo and Hunter,‖ did not suffice to bring about any radical change in the prevailing mode of practice; yet doubtless the recorded opinions of these eminent men were not without influence in the direction of moderation. Of still greater weight in the same direction were the teachings of Cullen: While admitting that it might sometimes be necessary to bleed vigorous patients at the beginning of the disease, and, even if inflammatory symptoms be present, to repeat the operation, he pointed out that the accompanying fever is apt to be of a putrid nature, and insisted upon the necessity of caution in this matter.¶

---

* L. BOTALLUS—*De Cur. per Sang. Missionem*, Lyons, 1577-80, Cap. 4; I cite Opera Omnia, Leyden, 1660, p. 132 *et seq.* The unfortunate advice of this celebrated advocate of bleeding has been only too extensively followed. He declared venesection to be not less desirable in dysentery than in pleurisy, and supported his position by elaborate arguments and by illustrative cases. SYDENHAM—Vol. I, p. 170, *op. cit.*, p. 407, *supra*—explains his practice in the following emphatic words: "As soon as I was sent for, I bled from the arm." Infants are to be treated in the same way, only with d fference of degree in the amount of blood drawn, p. 172. An instance of a woman afflicted with a chronic flux for three years, who was treated by repeated venesection only, will be found on p. 176.

† Already SENNERTUS—*loc. cit.*, last page—who still believed that by bleeding it was possible to evacuate the peccant humors, insisted especially upon its employment if fever be present, as well as if the dysentery proceeds from inflammation of the intestine, or if inflammation be threatened. He also insisted upon the importance of bloodletting if the liver be involved, (see RHAZES—*loc. cit.*, last page,) or if some accustomed flux is suppressed. So, likewise, ROLFINCIUS—*Epit. Meth. Cognosc.*, Jena, 1655, Lib. III, Cap. 17, p. 298—employed bloodletting when there was inflammation and fever, but only in symptomatic, not in critical dysentery. HOFFMANN—*Med. Rat. Syst.*, T. IV, Pars 3, Sect. 2, Cap. 7, Opera, Geneva, 1740, T. III, p. 158—declared an extensive experience had convinced him that bleeding is desirable at the beginning of the disease in plethoric persons. Among those who followed the current I may name RICHARD MEAD—*Monita et Præcepta Medica*, (1751,) Cap. VII, Sect. I; I cite Medical Works, Edinburgh, 1763, Vol. III, p. 61—who observed: "Wherefore, to come to the cure, the first thing to be done is to draw blood;" WILSON—*An essay on the autumnal dysentery*, London, 1761, p. 27; AKENSIDE—*De dys. comm.*, London, 1764, Cap. 2, p. 31; MACBRIDE—p. 465, *op. cit.*, p. 664, *supra;* BAKER—p. 25, *op. cit.*, p. 437, *supra;* STOLL—Pars III, p. 290, *op. cit.*, p. 242, *supra;* GEACH—p. 21, *op. cit.*, p. 660, *supra.*

‡ PRINGLE—Cap. 6, p. 260, 7th Ed., *op. cit.*, p. 640, *supra:* "Bleeding is sometimes indispensable, and indeed is generally conducive to the cure." Yet, to his credit be it said, he adds: "In weakly habits, and in contagion, with few feverish symptoms, I wholly omit that evacuation." DONALD MONRO—p. 68, *op. cit.*, p. 625, *supra:* "When the patients were strong, and complained of sharp pain of the bowels, attended with a fever, we used the lancet freely."

§ BONTIUS—*De Med. Indorum*, Leyden, 1718, (bound with the *Med. Ægypt.* of PROSPER ALPINUS,) Lib. III, Cap. 4, p. 66—bled, however, only in the hepatic flux, and remarks that the operation was not well borne by the Dutch at Batavia, because, on account of the heat of the climate, they were disposed to debility; hence he bled them only in cases of the greatest necessity; on the other hand, the Portuguese and Javanese, being inured to heat, bear large bleedings well, "expertus, credite, loquor." HILLARY—*Obs. on the Changes of the Air, etc., in the Island of Barbadoes*, (1759,) 2d Ed. London, 1766, p. 208—was more indiscriminate in his practice, remarking: "It is always necessary to take away some blood." MOSELEY—p. 229, *op. cit.*, p. 648, *supra*—in like manner observes: "Bleeding being an operation of great consequence in the flux, the cure is generally begun with it, repeating it as the symptoms authorise."

‖ DEGNER—Cap. 5, § 10, p. 267, *op. cit.*, p. 625, *supra.* His language is: "Ast venæ sectioni in nostro morbo nullus locus erat, nec eam in ullo, sive præservationis, sive curationis gratia, administrandam curavi; bilem enim non corrigit, sed potius vires vitæ frangit, et naturam in motibus suis salutaribus conturbat: unde vomitus cruentus et mors venæ sectionem cito sequebantur." ZIMMERMANN—Cap. 10, S. 380, *op. cit.*, p. 648, *supra*—admits, indeed, scholastically the propriety of bleeding in inflammatory dysentery, but held—S. 389—that it is unnecessary in bilious dysentery, and does not appear ever to have used it in the Swiss epidemic. ROLLO and HUNTER were both medical officers of the British army: J. ROLLO—*Obs. on the Acute Dysentery*, London, 1786, p. 46—"condemned venesection, because, he said, inflammation was not necessarily connected with the beginning of dysentery. When it was so, he declared, that it partook more of the erythematic or superficial kind, and was not associated with the inflammatory diathesis, but dependent on 'causes acting immediately on the interior surface of the intestine.'" I have not seen ROLLO's work, and cite from the essay of J. EWART—*A review of the treatment of tropical diseases*, The Indian Annals of Medical Science, No. XVI, 1863, p. 345. J. HUNTER—p. 237, *op. cit.*, p. 637, *supra*—observed: "All that I have learned on the subject amounts to this, that in slighter cases, or when the disease is treated early, purgatives have proved so effectual, that I have never had recourse to bleeding: and when the disease has been more violent, the strength of the patient has been so much reduced of a sudden, that I have not dared to make use of that evacuation."

¶ CULLEN—*First Lines*, § 1085, Vol. II, p. 327, Ed. cited p. 648, *supra:* "At the beginning of this disease, when the fever is any way considerable, bloodletting, in patients of tolerable vigour, may be proper and necessary; and when the pulse is full and hard, with other symptoms of an inflammatory disposition, bloodletting ought to be repeated. * * * But as the fever attending dysentery is often of a putrid kind, or does, in the course of the disease, become soon of that nature, bloodletting must be employed with great caution."

These conservative views were very generally accepted during the latter part of the last century and the beginning of this,* but the publication of the work of James Johnson (1813) was followed by a pretty general revival of the practice of Sydenham. Johnson advised a liberal resort to bleeding to be "employed without the smallest apprehension of that bugbear—debility."† Hennen, Somers and Bampfield adopted a similar practice, but even the freedom with which Botallus bled was exceeded by the frantic excesses of O'Halloran.‡ Not a few of the English physicians in the East Indies have followed the example of Johnson in this matter;§ and the influence of the doctrines of Broussais undoubtedly aided in maintaining the practice in Europe, where it has been defended by some able physicians until a comparatively recent period.‖ Meanwhile, however, the experience of the

* Thus J. P. FRANK—*De Cur. Hom. Morb. Epitome*, § 693, T. III, p. 448, Ed. cited p. 393, *supra*—advised to bleed, even to repeat the operation in the commencement of sthenic, but not in asthenic dysentery. So also PINEL—*Nos. Phil.*, T. II, p. 335, Ed. cited p. 605, *supra*—counselled bleeding only in dysentery complicated with inflammatory fever. FOURNIER et VAIDY—p. 374, *op. cit.*, p. 362, *supra*—held that bleeding may be necessary at the beginning of a simple dysentery, is essential in inflammatory dysentery—p. 391—but is not indicated in mucous and bilious dysentery, still less in adynamic dysentery, or dysentery complicated with typhus, p. 394 *et seq.* VIGNES—*Traité complet de la dysenterie et de la diarrhée*, Paris, 1825, p. 270—bled only if the inflammation was violent and in a robust subject.

† JAMES JOHNSON—*The Influence of Tropical Climates on European Constitutions;* I cite the 4th Ed., London, 1827, p. 218: "When blood appears alarmingly in the stools, whether the fever run high or not, venesection may be employed without the smallest apprehension of that bugbear—DEBILITY." According to EWART—p. 347, *op. cit.*, last page: "Dr. Whyte, in 1799, was among the first physicians who bled, repeatedly, to syncope, in dysentery." I find a *Copy of a letter to his Royal Highness, the Duke of York*, by D. WHYTE, surgeon to his Majesty's ship Atlas, dated Aug. 10, 1799, in the Medical and Physical Journal, Vol. II, 1799, p. 283, in which he urges bloodletting in the strongest manner, remarking: "I have frequently taken from forty to fifty and sixty ounces of blood in a couple of hours, and in so doing, saved many valuable lives." In the same journal, Vol. III, 1800, p. 232, is a second communication by WHYTE, in which this treatment is further commended. EWART—*loc. cit.*—adds that Dr. WHYTE'S "untimely end, produced by his having inoculated himself with the matter of a 'plague bubo,' induced his professional brethren and the public to consider his experimental venesections, ad deliquium, as emanating from 'a well meaning but hot headed medical enthusiast.'" I suppose it is to WHYTE, JOHNSON refers when he remarks—p. 213, note, *op cit., supra:* "Dr. White used the same venesectio ad deliquium, in Egypt, in 1802," but his further remark, "and Mr. White, a navy surgeon, published a work nearly a hundred years ago, in which he lays down a still more decisive system of bloodletting in dysentery," I have not been able to verify, though I have taken some pains to do so.

‡ J. HENNEN, in a letter written in September, 1815, to SOMERS—p. 50, *op. cit., infra*—observes: "Venæsectionem iteratam quamdiu dolor presso sentiretur abdomine vel sanguis floridus fæcibus commisceretur, remedium haud dubie potentissimum reperi et efficacissimum, cujus sane in hoc debellando morbo experimentum facere mihi contigerit." E. S. SOMERS—*Comm. quædam de dys.*, &c., London, 1816, p. 35—bled to sixteen ounces and repeated the operation daily for the first four days, after which, he naively remarks, he seldom found free bleeding necessary. R. W. BAMPFIELD—*A Practical Treatise on Tropical Dysentery*, London, 1819, p. 101 *et seq.*—declares: "I am able to prove its utility in tropical dysentery by the cases annexed," p. 102. In the preface to this work—p. ix—he exclaims: "If a human being be assailed by acute and active inflammation of an internal organ—whether he be shaking on the icy shores of Greenland or burning beneath the Equinox—whether he be a white or an Ethiopian—young or old, male or female, of a firm tone or relaxed, in the hot or cold season—what do these considerations avail? Is there any remedy so indispensably efficacious in its subduction as bleeding?" THOMAS O'HALLORAN—*Account of the diseases most prevalent in the 64th regiment during the year* 1818, *whilst stationed in Gibraltar*, The London Medical Repository, N. S., Vol. II, 1824, p. 205—placed his patients in the recumbent position and bled to syncope: "From thirty-two to sixty-four ounces of blood were usually taken at the first bleeding." He insisted "that a much greater degree of debility is produced by an uninterrupted disease of twenty-four or thirty-two hours duration, than succeeds to the loss of ten pounds of blood abstracted within the tenth hour from the period of attack." Even after such a first bleeding, as is mentioned above, he sometimes repeated the operation on the same day. On the second day he bled again, twenty to forty-eight ounces. He considered it important to produce syncope, and declared that the loss of five to six pounds of blood is often insufficient for the accomplishment of the object. This paper is unfinished; the reader will be glad to learn—p. 208, note—that the rest of it was accidentally destroyed by fire.

§ GEORGE BALLINGALL—*Pract. Obs. on Fever, Dysentery*, &c., Edinburgh, 1818, p. 67—remarks: "Of this remedy I have to express a very favourable opinion;" but, while stating that "of the few cases of dysentery in which I have employed bleeding, the majority have, I think, terminated favourably," he admits that he had been restrained from a free use of the lancet partly by the debilitated condition of the patients, but also by "a due deference to the opinion of the older practitioners in India, which, at the time of our arrival there, was almost universally against it." On which BAMPFIELD—p. ix, Preface *op. cit., supra*—comments: "Had Mr. Ballingall asserted the dignity of reason, and adopted 'a practice of which he expresses a very favorable opinion,' the author feels convinced he would not 'have dissected 100 subjects dead from this disease and witnessed many more.'" ANNESLEY—Vol. II, p. 273, *op. cit.*, p. 621, *supra*—advised bleeding in acute dysentery, "if the patient has recently arrived from Europe, if he be of a full habit, if the pulse be full, hard and irritable, if the tormina be violent, and pain fixed and increased on pressure;" he adds, "if the first bloodletting be sufficiently large, a repetition of the operation will be seldom necessary." Old residents and natives he did not bleed. In hepatic dysentery he thought general bloodletting usually required, and that it is often necessary to repeat the local abstraction of blood several times during the progress of the disease—p. 285—but he did not bleed in scorbutic dysentery or the chronic fluxes. TWINING—Vol. I, p. 69, *op. cit.*, p. 608, *supra*—bled more freely; sometimes repeating the operation two or three times. JAMES BANKIER—p. 114 *et seq.*, *op. cit.*, p. 637, *supra*—did so also, although he naively writes: "If dysentery, however, goes on, independent of three or four bleedings employed early in the attack, then I question very much if any good can result from the prosecution of the practice"—p. 126, *op. cit.* According to EWART—p. 356 *et seq.*, *op. cit.*, last page—J. MOUAT, (1831,) WALTER RALEIGH, (1834.) W. A. GREEN, (1837-40,) HUNTER, (1838,) JAMES BIRD (1839) and H. H. GOODEVE, (1842,) all bled with more or less freedom in Indian dysentery. PARKES—*Dysentery and Hepatitis of India*, London, 1846, p. 139—wrote: "For the purpose of subduing the inflammation, depletion is indispensably necessary in Europeans, and is indeed inculcated by all sound writers on the subject;" and again: "I cannot forbear again insisting upon the great importance of free depletion, general or local, according to the judgment of the physician, in the common acute tropical dysentery." Bloodletting, very much as practiced by ANNESLEY, is also still recommended by MOREHEAD—p. 293, *op. cit.*, p. 657, *supra*—and Sir JAMES RANALD MARTIN—p. 458, *op. cit.*, p. 621, *supra*. On the other hand, Professor W. C. MACLEAN—Vol. I, p. 120, *op. cit.*, p. 657, *supra*—assures us that at the time he wrote, bleeding, whether general or local, was almost entirely superseded in India by the ipecacuanha treatment, and AITKEN has added his testimony to the same effect; see note ‡, next page. Of the fact of the disuse of bleeding there can be no doubt, but I question the explanation offered.

‖ Among these I may mention NAUMANN—Bd. IV, Abth. 2, S. 94, *op. cit.*, p. 645, *supra;* VOGT—S. 171, *op. cit.*, p. 645, *supra;* COPLAND—*Dict. of Pract. Med.*, Vol. I, London, 1858, p. 717; and GEORGE B. WOOD—Vol. I, p. 719, *op. cit.*, p. 671, *supra*. The latter author expresses, as late as 1866, what had long been regarded as the conservative view on this subject: "Bleeding is not necessary in all cases of dysentery, and, in the adynamic form of the disease, may be injurious. It should, however, always be resorted to when there is much pain and tenderness of the abdomen, with febrile action and a vigorous pulse."

Wurtemburg epidemic convinced Hauff that the operation was seldom needed. Baly came to the same conclusion in the course of the epidemic at the Milbank penitentiary. Bamberger protested that he never had the courage to bleed during the Prague epidemic. Neither Trousseau nor Niemeyer so much as mention venesection in the account of the treatment of dysentery given in their text-books.* Savignac has declared that it is not indicated, and has drawn a deplorable picture of the consequences he witnessed at the beginning of his practice from the freedom with which it was then generally employed.† At present, as Heubner correctly states, venesection in this disease is universally abandoned; but it is erroneous to suppose, with Aitken, that this fortunate result is due to the revival of the use of ipecacuanha.‡ It is rather the result of the general reform which has led modern physicians to abandon this operation in the treatment of all inflammatory diseases. I may add that the new views had already been widely adopted in the United States before the commencement of our civil war, during the progress of which I did not hear of a single case in which venesection was resorted to in dysentery.§

One of the most distinguished medical writers in the United States has recently made an eloquent appeal in favor of the revival of bloodletting as a therapeutic agent.‖ A discussion of the general merits of such a proposal would be out of place here, but whatever its fortune, the hope may be expressed that no reaction will ever restore this operation to a place in the therapeutics of dysentery.

LOCAL BLOODLETTING.—The local abstraction of blood by means of cups was already practiced in the time of Hippocrates, and Galen discussed the employment of cups and leeches in a special treatise. It does not appear, however, that either of these physicians resorted to local bloodletting in the treatment of the alvine fluxes, and most of the other Greeks are equally silent on this head.¶ Themison, indeed, who has the credit of being

* HAUFF—S. 424, *op. cit.*, p. 534, *supra:* "Besonders wurde in der letzten Epidemie nach meiner eigenen und nach Anderer Erfahrung der Aderlass sehr selten und nur in der ausgebildet entzündlichen Form ertragen." Compare BALY—p. 525, *op. cit.*, p. 535, *supra.* BAMBERGER—S. 414, *op. cit.*, p. 578, *supra*—remarks: "Es fehlt mir an ausreichenden eigenen Erfahrungen über diese Methode, die selbst zu versuchen ich nicht den Muth hätte;" and he points out how vain it is to hope to limit exudative or ulcerative processes in the intestinal organs by the abstraction of blood. TROUSSEAU—T. III, p. 166 *et seq.*, *op. cit.*, p. 664, *supra.* NIEMEYER—Bd. II, S. 754 *et seq.*, *op. cit.*, p. 645, *supra.*

† SAVIGNAC—p. 331, *op. cit.*, p. 620, *supra:* "J'ai assisté, au début de ma carrière, aux derniers expériments de cette thérapeutique sanglante qui ouvrait les veines et lacérait la peau sous le moindre prétexte; * * * Les résultats étaient déplorables; les anhémies consécutives, les hydropisies, les cachexies étaient nombrenses, la chronicité plus fréquente, plus incurable," &c. HASPEL—T. II, p. 109 *et seq.*, *op. cit.*, p. 621, *supra*—has given a graphic account of the manner in which his Algerine experience compelled him to abandon bloodletting in dysentery, at the close of which he exclaims: "D'ailleurs par la saignée qu'allez-vous obtenir? Un état de faiblesse, de débilité générales? est-ce ainsi que vous pensez guérir en procédant comme la maladie? Non, plus le malade s'affaiblit, plus le mal grandit; l'expérience de chaque jour le démontre."

‡ HEUBNER—S. 543, *op. cit.*, p. 529, *supra:* "Der Aderlass, früher (von Sydenham, Broussais u. A.) viel angewandt, wird jetzt mit Recht vollständig vermieden." AITKEN—Vol. II, p. 659, *op. cit.*, p. 647, *supra:* "Bloodletting has now been totally superseded and rendered unnecessary by the use of ipecacuanha." But ipecacuanha was used with equal freedom in the latter part of the seventeenth and during the eighteenth century, even by those who bled extravagantly, as we will see hereafter.

§ In this connection I must commend the prudent remarks of STILLÉ—p. 363, *op. cit.*, p. 650, *supra*—which were doubtless not without influence upon our medical officers. He declares that under the use of antiphlogistic measures in dysentery "the strength is very apt to fail suddenly, and the disease to assume a low asthenic type. * * * Hence the apparently clear indication for venesection in the necessity of allaying the general violence of action and the local distress is calculated only to mislead, as it has done many physicians who afterward abandoned it as mischievous."

‖ S. D. GROSS—*A discourse on bloodletting considered as a therapeutic agent*, Trans. of the Amer. Med. Ass., Vol. XXVI, 1875, p. 419. In this address bloodletting is deplored as "one of the lost arts." The author declares that for nearly two thousand years it was regarded by the most eminent and enlightened men as essential to success in the treatment of disease. But the historical sketch just presented shows that this remark does not apply to the use of the operation in dysentery. Our modern practice in this disease is in harmony with that of the greatest of the Greek physicians, and is supported by the testimony of some of the best observers in every age. I cannot therefore believe that in this disease "bleeding will again come into fashion," p. 432.

¶ Both dry and wet cups are referred to in several passages in the Hippocratic writings; *e. g.*, in *De Medico*, § 7, [Ed. Littré, IX, p. 213,] both are described; wet cups in *De Morb. Intern.*, § 21, [*Id.*, VII, p. 221;] and dry cups in *Aphor.*, Sect. V, 50, [*Id.*, IV, p. 551.] The medical use of leeches is not referred to, although in *Prædict.*, Lib. II, § 17, [*Id.*, IX, p. 43,] the symptoms of a leech accidentally adhering in the throat are described. DIOSCORIDES—Lib. VI, Cap. XXXII, fol. 331, Ed. cited p. 623, *supra*—has a chapter on leeches, in which he describes the accidents to be apprehended from swallowing them with the drinking water, and gives details with regard to the treatment, but does not mention the use of leeches for medical purposes. According to CÆLIUS AURELIANUS—*Morb. Chron.*, Lib. I, Cap. 1, p. 285, Ed. cited p. 664, *supra*—the first to make use of leeches in the treatment of chronic diseases was THEMISON. This passage has been generally, and perhaps correctly, interpreted to mean that he was the first to employ them for any medical purpose; see, *e. g.*, SPRENGEL—Bd. II, S. 32, *op. cit.*, p. 346, *supra.* In the treatise of GALEN—*De Hirudinibus, Revulsione, Cucurbitula, Incisione et Scarificatione*, [Ed. Kühn, XI, p. 317,]—leeches are spoken of as a convenient substitute for cups. Their employment is also discussed by ORIBASE—*Collect. Med.*, Lib.

the first to employ leeches to abstract blood for medical purposes, is said to have applied them to the nostrils, ears and angles of the eyes of dysenterics; but Cælius Aurelianus, who reports this practice, criticises it as useless.* So, too, the application of both cups and leeches to the abdomen of patients suffering with the cœliac flux was directed by Aretæus, but only in case inflammation or distention should occur about the liver or stomach.† These are the only references to the use of local bloodletting in the treatment of the alvine fluxes that I have been able to find in the writings of the Greek physicians.

The Arabians used both cups and leeches more freely than the Greeks, and wrote at length on these methods of local depletion;‡ I find, however, no satisfactory evidence that they ever used leeches in diarrhœa or dysentery. The application, in certain cases of the latter disease, of wet cups over the sacrum, in the vicinity of the anus, or to the calves of the legs, is commended in the writings of Haly Abbas and Albucasis;§ but the Arabian physicians hesitated to affix wet cups to so tender a region as the abdomen, to which, however, they applied dry cups liberally in several forms of alvine flux; a practice especially commended by Avicenna.‖

It is difficult from the records in our possession to form any precise notion of the extent to which local bloodletting was actually employed in the treatment of the fluxes prior to the invention of printing, yet the doctrine so clearly expressed by Celsus, that wet cups may advantageously be substituted whenever the strength of the patient is insufficient to support venesection,¶ must have suggested at least the occasional employment of these local measures in the dysentery of children or feeble adults. Certainly we find this the general practice in the sixteenth century, as may be seen in the works of Altomarus and Nicolaus Piso.**

VII, Cap. 21 and 22, Œuvres, (Bussemaker et Daremberg,) T. II, Paris, 1854, p. 69 *et seq.*—in extracts borrowed from ANTYLLUS and MENEMACHUS, but he does not mention their use in the alvine fluxes. The same remark applies to his account of cups—*op. cit.*, Cap. 16-20, T. II, p. 58 *et seq.*—borrowed from various sources, and to the account of cups in the works of ÆTIUS—Tetrab. I, Serm. 3, Cap. 20, Lyons, 1549, p. 146—and PAULUS ÆGINETA—Lib. VI, Cap. 41, Vol. II, p. 324, Ed. cited p. 624, *supra*. ALEXANDER OF TRALLES is silent with regard to the use of either of these measures in the treatment of the fluxes, and the Roman writer, CELSUS, is likewise silent.

* CÆLIUS AURELIANUS—*Morb. Chron.*, Lib. IV, Cap. 6, p. 527, Ed. cited p. 664, *supra*.

† ARETÆUS—*De Cur. Morb. Diut.*, Lib. I, Cap. 7, Boerhaave's Ed., Leyden, 1731, p. 132: "And if there be distention or inflammation anywhere about the liver or mouth of the stomach, we are to apply the cupping instrument and scarify; and there are cases in which this alone is sufficient. But when, by means of cerates, the wounds have cicatrized and ended in hardness, we are to apply leeches."

‡ See, for example, on the subject of cupping and leeching, RHAZES—*Ad Mansor. De Re Med.*, Lib. VII, Cap. 22, De Cucurbitulis, Cap. 23, De Hyrudinibus, pp. 178 and 179, Ed. cited p. 678, *supra;* HALY ABBAS—*Pract.*, Lib. IX, Cap. 8, fol. 275, Ed. cited p. 678, *supra;* AVICENNA—Lib. I, Fen 4, Doct. 5, Cap. 21, De Ventosis, Cap. 22, De Sanguisugis, p. 225, Ed. cited p. 632, *supra;* ALBUCASIS—*De Chirurgia*, Lib. II, § 96, De Cucurbitulis, § 97, De Hirudinum Affixione, Oxford Ed., 1778, p. 491 *et seq.*

§ HALY ABBAS—*loc. cit.*—directs that wet cups (sitia cum incisione) be applied between the buttocks, (inter anchas,) *i. e.*, I suppose, over the sacrum, in tenesmus from inflammation of the lower bowel, (tenasmon apostemati,) and at the anus (super anum) in cases of pain or a sense of burning of that part, or of pain in the bowels. According to ALBUCASIS—p. 495, *op. cit.*, last note—a single large cup applied with free scarification (scarificet scarificatione magna) over the os coccygis is advantageous in case of ulcers of the lower bowels, (ulcera inferiora;) he adds that cups applied to both legs (to the calves?) diminish plethora in a striking manner, because they attract blood from the whole body; and in a passage, that does not exist in all the manuscripts, that this is advantageous in a flux of blood proceeding from dysentery; that the cups should be large, well scarified, and that strong suction should be used.

‖ The writers enumerated in note ‡ specify the various parts to which wet cups may be applied, among which none of them mention the abdomen. ALBUCASIS—p. 501, *op. cit.*—expressly directs that dry cups only (cucurbitulæ sine scarificatione) should be employed over the liver, the spleen, the umbilicus and other parts of the belly, &c., because wet cups are not well borne by these parts, (hæc etenim membra, in ea scarificationem non ferunt.) With regard to the application of dry cups in the treatment of the fluxes, see RHAZES—*Divisionum*, Lib. I, Cap. 67, p. 390, *op. cit.*, note ‡, *supra*—who recommends their application over the spleen (positio ventosarum cum igne super splenem) in the flux from black bile, and AVICENNA—Lib. III, Fen 16, Tract. 2, Cap. 5, p. 821, *op. cit.*, note ‡, *supra*. The latter author elsewhere—Lib. III, Fen 16, Tract. 1, Cap. 4, p. 816, *op. cit.*—strongly commends the application of dry cups to the belly in fluxes due to excoriation of the intestines, saying that he has known this treatment to cure the disease within four hours: "Et ex retinentibus fluxum ventris, est positio ventosarum super ventrem; jam enim expertum est, quod ventosæ positæ super ventrem eorum, qui habent fluxum ventris, et excoriationem quum dimittuntur quatuor horis, restringunt et nos jam experti sumus illud."

¶ CELSUS—Lib. II, Cap. II, Vol. I, p. 107, Ed. cited p. 656, *supra:* "Opus etiam esse cucurbitula potest in morbis longis, quamvis et iis jam spatium aliquod accessit; sive corrupta materia, sive spiritu male habente: in acutis quoque quibusdam, si et levari corpus debet, et ex vena sanguinem mitti vires non patiuntur. Idque auxilium ut minus vehemens, ita magis tutum," &c.

** DONATUS ANTONIUS AB ALTOMARI—*loc. cit.*, p. 680. *supra*—after laying down the rules for bleeding in the early stages of dysentery quite in accordance with the teachings of ÆTIUS and ALEXANDER OF TRALLES, ("prout Ætius, et Alexander probarunt,") adds that it is preferable to apply leeches to the arm in the case of children under eleven years old or to draw blood with cups, remarking: "Nam licet eis sanguis mittendus sit, si ea adsint, quæ supra notavimus, tamen iis non per venæ sectionem, sed per hirudines, aut cucurbitulas, extrahi debet." He does not state where the cups were to be applied, but this is clearly stated by NICOLAUS PISO—Lib. III, Cap. 15, p. 275, *op. cit.*, p. 665, *supra*—who, under the same circumstances, directs that blood be drawn by leeches applied to the arms, or cups to the buttocks or the shoulders: "Quod si ætas reluctetur, per hirudines admotas cubito, vel cucurbitulas clunibus et omoplatis adhibitas sanguis extrahatur."

According to these writers, leeches should preferably be applied to the arms, cups to the scapulæ or the buttocks. Fabricius Hildanus and Sennertus* employed the same method, but after Botallus and Sydenham† had popularized free venesection in the treatment of dysentery cups and leeches appear to have been very generally discarded as inefficient.‡ No mention is made of their employment in this disease by Pringle, Monro, Moseley or Cullen; and the majority of writers on dysentery, until the commencement of the present century, are equally silent.

When the use of cups and leeches in dysentery was again revived they were employed not merely as a substitute for venesection, but also as an additional means of depletion. The Arabian prejudice against applying wet cups to the abdomen no longer exercised any restraining influence, and this brutal mode of depletion, commended by various writers from Fournier and Vaidy to Barrallier, has been extensively used.§ I am sorry to say that it was resorted to by a few of our own medical officers during the civil war.‖ The application of wet cups to the sacral region, when pain in that part is complained of, or when rectal or vesical tenesmus is urgent, has also been approved by some physicians.¶ But, on the whole, during the present century preference has been given to leeches as a means of local bloodletting in dysentery, and cups have generally been employed only when economy was an object, or when leeches were difficult to obtain.

The application of leeches to the anus, proposed by Buchner in the early part of the last century, and approved by Pinel towards its close, was extravagantly praised by Broussais,** and came subsequently into very general use, especially in France. This plan has been commended by many modern writers, among others by Savignac, and quite recently by Heubner.†† It has been claimed that the congested circulation of the mucous membrane of the large intestine can in this way be directly depleted, which, in view of the anatomy

* FABRICIUS HILDANUS—Cap. 8, p. 684, *op. cit.*, p. 644, *supra*—remarks in the same connection: "In the case of children who, on account of their age, ought not to be bled, the arm should be tied up so as to make the veins somewhat prominent, then one or two leeches should be applied over a vein. In the case of the young, the old, and in all for whom the use of venesection may be doubtful, cups may be applied over the scapulæ for the sake of revulsion. At first they may be put on a few times without scarification; afterwards with scarification." SENNERTUS—T. III, p. 131, *op. cit.*, p. 645, *supra*—in the same spirit remarks: "If aught should prohibit venesection, cups with scarification should be applied to the scapulæ." He does not, however, mention the use of leeches in this connection.

† See p. 681, *supra*.

‡ Long before, CELSUS—*loc. cit.*, last page—had remarked, with regard to cups: "Cum eo tamen, ut sciamus, hic ut nullum periculum, ita levius præsidium esse."

§ FOURNIER et VAIDY—p. 392, *op. cit.*, p. 362, *supra:* "Les saignées locales faites, soit au moyen des sangsues posées à l'anus, soit par des ventouses appliquées sur l'abdomen, et scarifiées, sont souvent d'un grand avantage;" that is in the treatment of inflammatory dysentery. BARRALLIER—p. 769, *op. cit.*, p. 603, *supra:* "Dans les pays tempérés, quand les sujets ne sont pas trop débilités ou quand la maladie est récente, les saignées locales par les sangsues ou par les ventouses peuvent être prescrites dans la complication inflammatoire, pour combattre les douleurs abdominales parfois intenses." SAVIGNAC—p. 332, *op. cit.*, p. 620, *supra*—tells us that in his younger days it was common to see wet cups applied by the fifteen or twenty at a time to the abdomen; but the just censure which he bestows upon this method does not prevent him from advising on the very next page the application of from four to six wet cups over the course of the colon or in either iliac fossa, if the case is of a well marked inflammatory character or the tormina or tenesmus resists treatment. He declares that he prefers them to leeches.

‖ See, in Section II, the remarks of JONES—p. 85, *supra*—who declares that he never omitted the application of wet cups to the abdomen, "when the case assumed an aspect at all threatening," and that they were "uniformly beneficial;" and TAYLOR—p. 87, *supra*—who commended "wet cupping upon that portion of the abdomen where pressure caused the most pain" in the treatment of "ordinary cases" of dysenteric diarrhœa. I have no reason to believe that this practice was resorted to by any considerable number of our medical officers.

¶ Thus COPLAND—*loc. cit.*, p. 682, *supra*—directs: "If tenesmus or dysuria be urgent, and pain be felt along the sacrum, the leeches may be placed there or on the perinæum, or cupping on these parts may be directed."

** FELIX PLATER—*loc. cit.*, p. 680, *supra*—had noticed that spontaneous bleeding from pre-existing hæmorrhoids sometimes afforded considerable relief in dysentery, but, so far as I know, BUCHNER—*Miscell. Med. Phys. Mathemat.*, 1728, p. 1035; I have not seen this work, and cite from DEGNER, p. 186, *op. cit.*, p. 625, *supra*—was the first to use leeches for the same purpose. According to DEGNER he employed them with great success in epidemic dysentery when the tenesmus was severe and persisted in spite of other medication. PINEL—T. II, p. 335, *op. cit.*, p. 605, *supra*—only advised leeches to the anus in cases of dysentery complicated by suppression of an habitual hæmorrhoidal flux or of the menstrual secretion. BROUSSAIS—T. III, p. 213, note, *op. cit.*, p. 643, *supra*—declared that in the first stage of dysentery, when there is violent tenesmus and no feculent matters in the dejections, leeches applied to the anus relieve the disease in an almost miraculous manner. He did not, however, limit their application to this point, but also put them on over the cæcum, the epigastrium or any point along the course of the colon that might be painful. See notes to pp. 228 and 229, same vol.

†† SAVIGNAC—*loc. cit.*, note §, *supra*—regards leeches applied to the anus as perhaps even more useful than his favorite cups applied to the abdomen. He adds: "Ce moyen paraît avoir plus d'action sur l'inflammation de l'intestin, et il serait particulièrement indiqué dans le cas où l'intensité du ténesme et des épreintes l'emporterait sur celle des douleurs abdominales." HEUBNER—S. 543, *op. cit.*, p. 529, *supra:* "Besser ist die Blutentziehung am After, hier entleert man Gefässe, die mit denjenigen der erkrankten Schleimhaut in directem Connex stehen." He therefore advises the application, at the beginning of the disease, of 10 to 20 leeches around the anus.

of the parts, it is evident cannot possibly be effected by abstracting blood from the abdominal parietes. Certainly, if it is ever necessary or desirable to resort to local bloodletting in dysentery, this method might be expected to prove most advantageous; nevertheless, as Vogt has justly remarked, experience shows that the general course of the disease cannot thus be perceptibly modified, and the fetid discharges from the bowels are apt to contaminate the leech bites around the anus and convert them into ugly sores.*

Various other parts have been selected for the application of leeches in dysentery, such as the sacral region, the upper part of the inner surface of the thighs and the lumbar region; this latter was preferred by Vignes,† under the delusion that he could thus deplete from the intestines through the mesentery; but the general practice has been to apply them directly to the surface of the abdomen. Here some, with Hauff and Naumann,‡ have selected the course of the large intestine; others, with Twining,§ the part most sensitive to pressure, wherever that may be. Both Annesley and Twining‖ used them to secure further depletion after the employment of venesection as well as in cases where general bloodletting was contraindicated, and this practice was adopted by many later Indian physicians as well as by some of the best European practitioners. The prevalent belief in the efficacy of bloodletting in inflammation encouraged not a few to go to dangerous extremes, both in applying great numbers of leeches and in permitting subsequent hæmorrhage from the bites. Cheyne declared in 1822 that he had known patients to die from such hæmorrhages; and Savignac,¶ writing of a much later period, testified that he had seen forty, sixty, even a hundred leeches applied to the belly at a time. Such wanton extravagances have disappeared from practice since the abandonment of bloodletting, but the application of a moderate number of leeches, in case the tormina are severe, or if there is much tenderness on pressure, continues to find favor in many quarters. Even so prudent a physician as Niemeyer commends this practice; nay, he goes further and sanctions subsequent warm applications to favor hæmorrhage from the bites.**

Is this practice necessary or justifiable? I cannot think so. If a sufficient quantity of blood be drawn in this way to produce any constitutional impression, it can only diminish the natural powers of resistance and thus indirectly add to the dangers of the disease. If less be taken, no beneficial modification of the inflammation is produced; and any temporary relief from pain that can be thus obtained might with less inconvenience be secured by morphia, administered hypodermically, or other unobjectionable means. Bamberger, who more than twenty years ago expressed substantially these views, nevertheless admitted the propriety of local bloodletting in case the symptoms clearly indicated the existence of local peritonitis; and Heubner†† has recently expressed the same opinion. I cannot, however,

---

* VOGT—S. 174, *op. cit.*, p. 645, *supra*. He admits, however, that the tenesmus is more likely to be relieved in this way than by the abstraction of blood, even in greater quantity, from other parts. BAMBERGER—S. 414, *op. cit.*, p. 578, *supra*—asserts, however, that the tenesmus can be still more effectually relieved by the use of narcotics; in which he is undoubtedly right.

† This application to the sacral region is mentioned by COPLAND—*loc. cit.*, last page; see also VIGNES—*loc. cit.*, p. 682, *supra*—who applied leeches both to the thighs and the lumbar region; his reasons for preferring the latter situation are given in a foot note.

‡ HAUFF—S. 442, *op. cit.*, p. 534, *supra*—advised leeches only in inflammatory dysentery to be applied to the most painful part of the abdomen, "which as a rule will be the region of the descending colon." NAUMANN—Bd. IV, Abth. 2, S. 95, *op. cit.*, p. 645, *supra*—indicated as preferable the region of the cæcum and of the descending colon.

§ TWINING—Vol. I, p. 70, *op. cit.*, p. 668, *supra*. ‖ ANNESLEY—Vol. II, p. 273, *op. cit.*, p. 621, *supra*. TWINING—see last note.

¶ J. CHEYNE—*Med. report of the Whitworth Hospital, House of Industry, &c.*, The Dublin Hospital Reports, Vol. III, 1822, p. 47: "But it must be observed that the effusion of blood after leeches applied to the abdomen, when the patient is exhausted, ought to be watched: I have known patients when neglected, sink in consequence of this effusion, who would have borne a moderate bleeding well." SAVIGNAC—*loc. cit.*, p. 683, *supra*.

** NIEMEYER—Ed. II, S. 753, *op. cit.*, p. 645, *supra*. This treatment he declares is most serviceable, ("leistet vorzügliche Dienste.")

†† BAMBERGER—*loc. cit.*, note *, *supra*: "Nur bei localen umschriebenen Entzündungen des Bauchfellüberzugs bringen, wie diess oben angedeutet wurde, örtliche Blutentziehungen häufig Erleichterung." So, also, HEUBNER—*loc. cit.*, last page—says of local bloodletting applied to the abdomen: "Man hat sie deshalb auf die Fälle excessiver Schmerzen und peritonitischer Erscheinungen zu beschränken."

admit that this complication offers any peculiarities to justify such treatment. No more in this than in other inflammations is any considerable loss of blood aught but injurious; no more than in others is a more moderate abstraction aught but inefficient. I am fully in accord with those who, like Bauer,* have of late counselled that in peritonitis, whether general or circumscribed, local as well as general bloodletting should be abandoned, for it is a delusion to imagine that we can by their means either check or modify for the better the course of the disease.

MEDICATION BY THE MOUTH.—For the cure of the alvine fluxes physicians have employed an immense variety of medicaments which may, however, be conveniently grouped under a few general heads. Changes of opinion with regard to the pathology of these diseases have by no means been always accompanied by radical modifications of the therapeutical measures adopted, some of which are still found practically useful after having been employed on various theoretical grounds for more than two thousand years. This statement is well illustrated by the history of the treatment of dysentery. So long as the humoral pathology maintained its sway there could be no doubt as to the indications;† the acrid humors, regarded as the cause, should be evacuated from the alimentary canal by purgatives and emetics, from the blood by diaphoretics and diuretics; meanwhile their injurious action upon the intestines should be moderated by the administration of diluents and emollients, or the mucous membrane protected by glutinous and oily substances; the

* BAUER—*Krankheiten des Peritonæums*, Ziemssen's Handb., Bd. VIII, 2, S. 355—after stating that the approved treatment of peritonitis has consisted in venesection, the application of leeches to the part, inunctions with mercurial ointment, sometimes to salivation, and the internal administration of calomel, adds: "I must avow that I have not been able to recognize any demonstrable success from these things; that on the contrary the free abstraction of blood from the abdomen by 50 or more leeches must produce an injurious effect on the circulation. At most it may be claimed for a smaller number of leeches (15–20) that the subjective sensations are improved without any injurious consequence resulting. But I believe that in most cases the practitioner may omit local bloodletting without being guilty of neglect." In striking contrast with these temperate views are those expressed in a recently published lecture by my friend H. C. WOOD, JR.—*The heroic treatment of idiopathic peritonitis*, The Boston Med. and Surg. Jour., Vol. XCVIII, 1878, p. 556: "I remember my uncle, Dr. George B. Wood, saying that he never lost a case of peritonitis in an adult, and the reason he gave was that he always bled his patients from the arm until they fainted, and then put one hundred leeches on the abdomen. I am proud to say that I am a thorough believer in the same plan of treatment, antiquated as it may appear. * * * I have never, you see, had cause to regret having bled my patients copiously. It makes very little difference whether you take the blood from the arm or from the abdomen, provided you draw enough to make a profound impression. * * * What is to be done after venesection? I take my stand on the old theory that calomel has power to modify inflammatory action. * * * I am, as you see, a most entire believer in the antiphlogistic properties of calomel,—not indeed in inflammations where there is too little fibrine, but in all inflammations where it is in excess. As peritonitis is an exceedingly severe disease, and means death in ninety-nine out of a hundred cases unless they are treated promptly and efficiently, mercury, to do any good, must be taken in decided doses. In my fifth case, referred to above, I gave half a grain of calomel every hour. In this case I am giving one quarter of a grain every hour. In connection with the calomel opium is undeniably of great value. * * * The ability to stand large doses of opium in peritonitis is wonderful. In one of my cases *seventy-five* grains of solid opium were taken daily for five days, and the patient made an excellent recovery. * * * After the abdomen has been thoroughly poulticed for two or three days blisters may be used, provided the temperature of the body has not remained high; that is, a blister may be applied at the end of three days if the temperature has fallen in the mean while. Do not put on a small blister. I was talking with my uncle, Dr. George B. Wood, the other evening about this very case, and he said that if he were in my place he would order a blister ten by ten (inches). I have ordered a blister eight by ten." Is such treatment wise? Is it true that bleeding, followed by calomel and opium in large doses, cures peritoneal inflammation? If so, why not all other inflammations, including those that follow surgical injuries? Are we to throw away all the experience of the last twenty years in this direction? Shall we not rather regard the plan of treatment recommended in this lecture as a relic of the past, no more to be accepted than the statement that peritonitis "means death in ninety-nine out of a hundred cases unless they are treated promptly and efficiently?"

† I will not pause here to collect the indications insisted upon by the ancients, which will be sufficiently shown further on in connection with the several groups of remedies, but cite, in illustration of those recognized by the more modern humoralists, FELIX PLATER—p. 808. *op. cit.*, p. 680, *supra*—according to whom the objects to be attained in the treatment of all the alvine fluxes are: 1, To remove the cause, whether it is to be found in bile or other morbid humor, in eroding medicaments or in poisons; this is to be effected by evacuants and abstergents. 2, To diminish the violence of its action by lenitives, anodynes, stupefaciants and antidotes, and, if inflammation be also present, to use refrigerants. 3, To endeavor to heal the excoriations and ulcers, which constitute the disease, by drying remedies, and especially to use astringents, which not merely have this effect but also check the flux. FAB. HILDANUS—p. 675, *op. cit.*, p. 644, *supra*, writes: "The chief points in the treatment of dysentery are that the acrid and malignant humor should be evacuated, and the ulceration and excoriation healed. Meanwhile, as Galen admonishes, attention should always be paid to the condition of the liver, (GALEN—*Comm. IV in Hippoc. de Artic Lib.*, Cap. 39, [Ed. Kühn, XVIII, A, p. 730.]) That this may be effected four indications (intentiones) should be observed: 1, That a proper regimen should be adopted; 2, that acrid and malignant humors should be purged away and evacuated; 3, that the pains should be mitigated; and 4, that the flux should be checked and the ulcers healed." SENNERTUS—T. III, p. 131, *op. cit.*, p. 645, *supra*—remarks that in the treatment of dysentery the indication is to heal the abraded or ulcerated intestine; but that since this cannot be done unless the cause is first removed, the abrading, eroding humor should be evacuated and absterged, at the same time its acrimony mitigated and corrected; other humors should be prevented from flowing to the intestines, by revulsion and derivation; the flux should be checked by astringents, and the pain, if vehement, lenified and removed. In like manner, too, BOERHAAVE wrote—*Aphorismi*, (1709,) § 722, Nuremburg, 1747, p. 159: "Sanatio absolvitur acris irritantis lenimine; expulsu per emetica, purgantia, clysmata; corroboratione laxi; pacatione impetus per narcotica; determinatione aliorsum per sudores, urinasve; subductione materiæ morbosæ, correctio ejus fonte primo;" on which see the learned commentary of VAN SWIETEN—T. II, p. 387, *op. cit.*, p. 663, *supra*—in which the judicious reader will find much worthy of reflection.

pain should be controlled by anodynes, and after the evacuation of the morbid humors the flux should be checked by astringents and the strength sustained by corroborants. But substantially these very measures continued to be resorted to by those who announced that the efforts of the physician ought chiefly to be directed to the cure of the inflammation of the intestinal mucous membrane, and they are still resorted to with but little modification by those modern practitioners who, like Niemeyer, declare that it is vain to attempt to meet any *indicatio causalis* or *indicatio morbi*, and that all we can do is to endeavor to fulfil the *indicatio symptomatica*.*

Much briefer has been the popularity of the various remedies supposed to possess specific virtues, which from time to time have enjoyed temporary favor, but presently fallen into disuse, to be replaced by others. Most of these belong to the groups of therapeutic agents just indicated, or are compounded by combining articles belonging to several of them; some, however, are derived from other classes of drugs. It cannot be said that any of them actually deserve the reputation they have enjoyed. The same remark applies to the various plans which have been suggested for jugulating or aborting acute dysentery at its onset.† No more in this than in other acute inflammations are we so fortunate as to have means that really possess any such power.

In determining upon the plan of treatment for any particular case of flux it should be borne in mind that the acute forms, including even diphtheritic dysentery, are, under favorable circumstances, like other inflammations, self-limited as to duration, and tend towards recovery. This latter tendency exists also to a greater or less extent in the chronic cases, except when some fatal constitutional complication coexists, or after an actual destruction of the intestinal mucous membrane to an extent incompatible with recovery has already occurred. A system of therapeutics directed merely by the indications afforded by the symptoms will often lead to the adoption of inefficient or even of dangerous medication: much rather should the practitioner always endeavor to recognize the pathological conditions actually existing in each case, and consider the probable effects of any proposed plan of treatment upon these conditions, selecting only those remedies which are favorable to the natural tendency to resolution, and rejecting all those which could have the effect of aggravating the lesions present. Already the Greek physicians endeavored to regulate their treatment of the fluxes in accordance with the part of the intestine affected and the character of the local process.‡ Whatever want of success attended this effort was due to the imperfect pathological knowledge upon which their diagnosis of the local condition was

* NIEMEYER—Bd. II, S. 755, *op. cit.*, p. 645, *supra*.

† Or, as the Germans call it, "Abschneidungskur." See VOGT—S. 163, *et seq.*, *op. cit.*, p. 645, *supra*—who enumerated under this head attempts to cut the disease short by large doses of ipecacuanha; by free purgation, especially with large doses of calomel; by combinations of calomel and ipecacuanha, both in large doses; and by free diaphoresis produced by the warm bath and covering the patient with many bed clothes, as well as by the administration of diaphoretics, hot drinks, &c. Compare BAMBERGER—S. 413, *op. cit.*, p. 578, *supra*—who speaks of such measures under the heading "Abortivemethode," enumerating energetic diaphoretic measures, emetics and large doses of calomel as having been resorted to.

‡ Thus the Greek physicians attached great importance to the symptoms by which they hoped to diagnosticate between abrasion and ulceration of the small intestine and of the large: see note †, p. 362, *supra*, for details. In the first case they advised that remedies should be administered by the mouth; in the second case by enemata. Again, in the Hippocratic writings it is clearly indicated that the diluent and mild astringent drinks, which answer well enough for simple (catarrhal) dysentery, are inadequate for the treatment of the severer (diphtheritic) cases in which pseudomembranes and sloughs (*ξύσματα*) occur in the stools; in this grave form of the disease purgation should first be resorted to—see Aph. VII, 69, [HIPPOCRATIS *Opera*, Ed. Kühn, III, p. 765:] "Et quibus dejectiones, si residere permiseris neque moveris, veluti strigmenta subsident, *et si paucæ sunt, parvus est morbus, sin vero multæ, magnus*, iis alvum infra purgari conducit. Quod si minime purgata alvo sorbitiones exhibueris, quo plures dederis, eo magis nocebis." GALEN, in his commentary on this passage, [Ed. Kühn, XVIII, A, p. 182,] holds that the text is probably corrupted, and asserts that it is by no means always necessary to purge if *ξύσματα* are present in the stools; in fact, as will be shown hereafter, he objected in a general way to purgation in dysentery. LITTRÉ [IV, p. 601] omits the passage I have italicized in the Hippocratic aphorism, chiefly on account of its absence from an ancient manuscript, (which he designates C'.) but he correctly remarks that the same idea is expressed in aphorism VII, 81, as to the authenticity of which he has no doubt; it will also be found in the treatise *De Judicationibus*, § 32, [Ed. Littré, IX, p. 287,] so that there can be no doubt of the importance attached in the Hippocratic times to the presence or absence of *ξύσματα* in the stools. Now that we better understand the nature of these substances, their diagnostic value is still greater, and modern physicians would do well to imitate HIPPOCRATES in attention to the characters of the stools.

founded. A similar attempt ought to be attended with better fortune at the present time, when we possess so many aids to accurate diagnosis which were quite unknown to them. This purpose, therefore, will be kept in view in the course of the remarks about to be offered with regard to particular medicaments.

EMETICS.—The virtues of white hellebore, administered as a phlegmagogue-emetic in the early stages of dysentery, are extolled in the Hippocratic writings.* Galen administered emetics in dysentery to evacuate peccant humors accumulated in the stomach, and as revulsives when the lower bowels were ulcerated, or in chronic diarrhœa.† Archigenes employed them for similar reasons in the cœliac flux, and affirms that they serve to restore the normal functions of the digestive organs.‡ The usefulness of revulsion thus produced, in the treatment of the alvine fluxes, is commended in the Canon of Avicenna.§ Altomarus, Amatus Lusitanus, Fab. Hildanus, Riverius and Rolfincius employed emetics in the early stages of dysentery,‖ but we learn from Forestus that the physicians of his times were divided in opinion as to their use; he himself held that if the patient could readily be vomited, if his stomach were not very weak, and he had no great loathing for food, mild emetics are advantageous.¶ Felix Plater limited the exhibition of emetics to cases in which the stomach contained morbid humors or poisons, and Sennertus strenuously advised that they should be used only in the latter case.** Meanwhile, however, two drugs came into use which subsequently acquired great renown as specifics, and may conveniently be considered in this place, although the advocates of each have strenuously denied that its virtues in this disease are due to its emetic action: I refer to antimony and ipecacuanha.

Antimony, which had been lauded by the alchymist Basil Valentine as a cure-all, was almost equally extolled by Paracelsus, who invented a nostrum in which it was the most potent ingredient for the cure of desperate cases of dysentery.†† The Paracelsists and iatro-chemists used a great variety of antimonial preparations in this disease, both as specifics and on account of their energetic diaphoretic action, while Sylvius claimed for them peculiar alterative powers as well as unequalled virtues in evacuating bile, phlegm

* See the account of the treatment of dysentery in the Hippocratic treatise *De Affectionibus*, § 23, [Ed. Littré, VI, p. 235:] "After having purged the head," [by errhines, because the flux proceeds primarily from the head?] "give a phlegmagogue-emetic, then having cleansed the belly with boiled milk," [by enemata?] "care for the rest of the body." Further on—p. 237—a similar treatment is ordered for chronic diarrhœa, and it is explained that the phlegmagogue-emetic meant is hellebore.

† GALEN—*Comm. VI in Hippoc. Epidem. VI*, § 5, [Ed. Kühn, XVII, B, p. 329:] "At in superiore ventre et maxime in ejus ostiolo id genus contractis humoribus in primis eos vomere jubemus;" also *Meth. Med.*, Lib. IV, Cap. 6, [*Id.*, X, p. 291:] "Quare nunc quoque, si etiamnum fluxio valenter irruat, ad contraria revellemus, utique si in superioribus ulcus consistat, per inferna purgantes; sin autem in inferioribus sit, superiorem ventrem vacuantes." Compare HIPPOCRATES—*Aph. VI*, 15, [Ed. Littré, IV, p. 567:] "The vomiting which supervenes spontaneously in a chronic diarrhœa, cures it." On which GALEN comments [Ed. Kühn, XVIII, A, p. 24] that this is one of those cases in which the operations of nature ought to be imitated by the physician, and that such treatment proves useful by revulsion.

‡ ARCHIGENES, in ÆTIUS—Tetrab. III, Serm. 1, Cap. 37, p. 590, Ed. cited p. 656, *supra:* "Mirabiliter etiam vomitus efficaces sunt, tum a cœna, tum jejunio facti, nimirum quæ corrupta sunt evacuantes, et quæ ad intestina dilapsa sunt attrahentes et converrentes, ac proprias ventris actiones revocantes." In ÆTIUS they are also commended in the early stages of dysentery following the ingestion of poisons—Tetrab. III, Serm. 1, Cap. 45, p. 608, Ed. cited—and in lientery—Tetrab. III, Serm. 1, Cap. 51, p. 618, Ed. cited.

§ AVICENNA—Lib. III, Fen 16, Tract. I, Cap. 4, p. 815, Ed. cited p. 632, *supra:* "Et iterum quandoque curatur fluxus ventris cum diureticis, et sudorem facientibus, et dilatantibus poros, et vomitum facientibus: omnia namque hæc movent materiam ad contrariam partem fluxus ventris." The practice indicated in this passage was long approved by the majority of physicians.

‖ ALTOMARUS—fol. 183, *op. cit.*, p. 680, *supra;* AMATUS LUSITANUS—*Cur. Med.*, Cent. II, Cur. 44, p. 285, Ed. cited p. 656, *supra;* FAB. HILDANUS—Cap. 8, p. 683, *op. cit.*, p. 644, *supra;* RIVERIUS—*Prax. Med.*, Lib. X, Cap. 6, p. 302, *op. cit.*, p. 680, *supra*—adds that ANGELUS SALA used salt of vitriol in half-drachm or drachm doses for this purpose; ROLFINCIUS—*Epit. Meth. Cognosc.*, Lib. III, Cap. 17, p. 298, Ed. cited p. 681, *supra*—commends emetics, especially if the ulcer is in the upper intestines.

¶ FORESTUS—*Obs. et Cur. Med.*, Lib. XXII, Obs. 34, Scholia, p. 379, Ed. cited p. 680, *supra.*

** FELIX PLATER—T. III, p. 810, *op. cit.*, p. 680, *supra;* SENNERTUS—T. III, p. 174, *op. cit.*, p. 645, *supra.*

†† BASIL VALENTINE—*Currus Triumphalis Antimonii;* I have seen only the English version, London, 1661: "Verily out of antimony may be prepared a medicine, (but all its venenosity must be first changed into medicine) which may be able to blot out and consume all diseases." p. 53. Among the diseases specified are phthisis, asthma, lepra, the plague, jaundice, dropsy, all fevers, &c.: "It comforts the head, the brain, and what is of affinity to them, the stomack, the liver; it heales the diseases of the reines, it purgeth corrupt bloud, expels maligne humours," &c., p. 173. I find, however, no specific mention of dysentery. PARACELSUS—*Parag.*, Lib. I, Cap. 1, Par. 5, T. I, p. 492, *op. cit.*, p. 336, *supra*—advised that if dysentery prove obdurate and likely to become chronic a "*laudanum*" should be used, consisting of finely divided (drawn or leaf) gold, pearls, asphaltum, flowers of antimony, oriental crocus, myrrh and aloes. The same formula is repeated in Lib. I, *Par., Comm.*, p. 540, *op. cit.*, as suitable for desperate cases, ("dissolutis jam deploratis utere isto laudano.")

and other peccant humors from the body by purging as well as by vomiting.* Early in the eighteenth century a Scotch minister named Steel used a secret remedy for dysentery, the receipt for which, about 1724, fell into the possession of Dr. George Young, who made it public. It was known at first as the stibium specificum, or as Young's antidysenteric powder, afterwards as the cerated glass of antimony, (vitrium antimonii ceratum.) In 1736 the celebrated Pringle read a discourse before the Edinburgh society for improving natural knowledge, in which he claimed for this preparation that it was a genuine specific for dysentery, and this not because of its emetic or purgative properties, for it sometimes cured without producing any evacuation. He supported his opinions by the testimony of Young and other practitioners who had used the drug.† The reputation of this medicine soon spread throughout Europe, though it appears to have been used more generally by the English than by the continental physicians; but it was found to be uncertain in its action and often dangerous, so that after a dazzling but brief popularity it fell into disuse. Pringle himself lived to abandon it.‡

Meanwhile similar objections were urged against the use of any of the antimonials: Van Swieten regarded them as objectionable because of the great perturbation they produced; Degner insisted that after taking them corrosions and even more serious lesions of the intestines were to be dreaded.§ Nevertheless, as will be shown when diaphoretic measures come to be discussed, the employment of certain antimonial preparations to

* F. DE LE BOE SYLVIUS—*De Meth. Med.*, Lib. II, Cap. 10, § 39–42, Opera, Amsterdam, 1679: "Ex antimonio infinita fere parantur vomitoria; quæque omnia simul sunt purgantia per alvum; quæ omnes educere solent humores in corpore peccantes, bilem, pituitam, et quodvis serum; adeo ut non putem ullum reperiri in rerum natura medicamentum ipsi antimonio æquiparandum; postquam non tantum omnis generis evacuantia, sed et alterantia ex ipso queunt parari; unde si aliqua reperiatur in rerum natura materia, ex qua parari possit medicamentum universale, morbos quosvis ab humorum vitiis pendentes curans, illa revera sit antimonium, quod ex parte saltem expertus loquor," § 30, p. 104. Yet it may be noted that it is only the so called "diaphoretic antimony" that appears in any of his formulæ for the treatment of the fluxes—*Prax. Med.*, Lib. I, Cap. 13, § 53, *op. cit.*, p. 183. I have not thought it worth while to collect other authorities with regard to the use of the antimonials in dysentery by the iatro-chemists. DEGNER—Cap. III, § 13, p. 129, *op. cit.*, p. 625, *supra*—mentions the crocus metallorum, the glass of antimony, tartar emetic and sulphur of antimony as having been thus used. The curious reader will find an account of the various antimonial preparations in use in the early part of the eighteenth century in the *Medicinal Dictionary* of JAMES, Vol. I, London, 1743, Art. Antimonium, and in the various essays collected under the head Antimoine in the *Bibl. Choisie de Méd.* of PLANQUE, T. II, Paris, 1749, p. 488 *et seq.*

† JOHN PRINGLE—*Vitrum antimonii ceratum, a specific medicine in the dysentery*, Med. Essays and Obs. published by a society in Edinburgh, Vol. V, Part 1, 1742, p. 194 *et seq.* The preparation was made, according to YOUNG, by melting together an ounce of glass of antimony and a drachm of beeswax in an iron ladle, and, after stirring them together for half an hour over a slow fire, the resulting mass was cooled and powdered. The dose for an adult was 10 to 20 grains, p. 198. PRINGLE adds the favorable testimony of his uncle, FRANCIS PRINGLE, and several other practitioners.

‡ MACBRIDE—*loc. cit.*, p. 664, *supra*—wrote in 1771: "The vitrum antimonii ceratum, which was once so highly extolled, appears to have gone out of use on account of the extreme uncertainty of its operation, which, it must be confessed, is the fault of all antimonial preparations; nevertheless, in cases where the remedies proposed shall be found ineffectual, it ought to be tried." So, too, MOSELEY—p. 257, *op. cit.*, p. 648, *supra*—wrote: "After the cerated glass of antimony had been introduced into public practice, in the dysentery, its reputation soon spread over all Europe; but from the unguarded manner of giving it, while the patient was exposed, and walking about, without more restriction than was used in a common vomit, or purge, it was always dangerous, and it soon sunk into discredit." He held that the common glass of antimony was to be preferred, and even this, in his London practice, he finally abandoned for ipecacuanha, p. 253. PRINGLE already, in the first edition of his *Obs. on the Dis. of the Army*, London, 1752, p. 278, confessed that "notwithstanding I was convinced of its being a powerful remedy, yet the operation being always rough, I could not avoid being anxious about the event;" and adds: "Another inconvenience attends this medicine, common to all antimonials; which is the difficulty of making it to a standard. Hence it happens, that a moderate dose at one time, will be too little or excessive at another." He therefore used ipecacuanha as an emetic after bleeding, but thought that "there can be no harm in adding a grain or two of emetic tartar to a scruple of ipecacuanha; whereby the virtues of the root will be retained, and the medicine rendered more purgative and efficacious in evacuating the bile." In the 4th edition of his work, London, 1764, p. 270, and in subsequent editions, he explains his reasons for abandoning his "specific:" for "the roughness of its operation, and the prejudice conceived against the glass of antimony, as a medicine, having deterred the other physicians of the army, and the regimental surgeons from using it, I also desisted."

§ From the very first, indeed, the antimonial preparations met with a crowd of opponents. The faculty of medicine of Paris early condemned their use, and in 1566 the Parliament of Paris issued a decree forbidding physicians to employ them; see PLANQUE—T. II, p. 516, *op. cit.*, note *, *supra*—and SPRENGEL—Bd. III, S. 264, u. 546, *op. cit.*, p. 346, *supra*. This decree appears to have been unconsciously imitated by Surgeon General W. A. HAMMOND in his circular of May 4, 1863, by which tartar emetic and calomel were struck from the supply table of the army; (those who have deplored this order will be interested to learn from the statement of Surgeon W. C. SPENCER, U. S. A., that notwithstanding it, 21,804 ounces of tartar emetic were actually purchased for our army during the civil war.) The French decree differed, however, from this circular in the serious character of the penalties attached. In the year 1609 a physician, named BESNIER, was expelled from the faculty of medicine for having ventured to disobey it. (PLANQUE—*loc. cit.*—states that it was PAULMIER who was expelled for this reason in 1609, but according to SPRENGEL, although PAULMIER was summoned before the faculty in 1608 for having published a tract in which he defended the use of the antimonial preparations, he was excused on recanting his error.) But in spite of the penalty physicians continued to use antimony for various purposes. In the year 1637 its advocates succeeded in having it placed among the purgatives in the "Anti-dotaire" prepared in that year by order of the faculty, and although the extent to which this authorized its employment gave rise to subsequent disputes, it gradually came into common use—PLANQUE, *loc. cit.* Undoubtedly the introduction of ipecacuanha had much to do with causing the discontinuance of the use of antimonials in dysentery. VAN SWIETEN—T. II, § 722, p. 390, *op. cit.*, p. 663, *supra*: "Quamvis tamen ipecacuanha merito summo in usu sit, quia non tam valide corpus turbat, quam antimonialia vomitoria; et tuto etiam infantibus dari potest." DEGNER—*loc. cit.*, note *, *supra*—in a foot note adds that all the antimonial emetics possess caustic and drastic properties, and that they frequently give rise to fatal hypercatharsis.

provoke sweating continued to find favor in some quarters;* and tartar emetic, which Baker preferred to ipecacuanha, and Pringle and Macbride combined with it to make its action more energetic, continued to be occasionally employed as an emetic in dysentery until a comparatively recent period.† Tartar emetic was also sometimes combined with the saline cathartics either in considerable doses to produce an emeto-cathartic action, or in smaller proportion with the view of increasing the energy of the cathartic and of favoring the evacuation of bile.‡ Such a combination, long since commended by Sir Gilbert Blane and Bampfield, enjoyed a considerable popularity at the commencement of our civil war in consequence of the teachings of Surgeon C. S. Tripler, U. S. A.§

But in dysentery the addition of tartar emetic to the other remedies employed, as well as its use alone, may well be regarded with distrust. Its tendency to irritate the gastro-intestinal mucous membrane seems to be clearly established, and even when administered in moderate doses it sometimes unexpectedly gives rise to local inflammatory processes. When small doses are repeated at intervals for some time, or large doses are given, these accidents are still more common.‖ Nothing then could justify the administration of tartar emetic in dysentery or the other fluxes unless it could be shown to exert some favorable influence upon the progress of the disease that cannot be obtained in any other way. But all the effects which we are warranted by evidence in attributing to it may be obtained by other medicaments that are much less likely to aggravate the already existing intestinal lesion. Accordingly the use of antimonials in the fluxes, which during the last half century has been becoming less and less general, has fallen at last into deserved oblivion.

---

* See remarks below under the head of diaphoretics.

† BAKER—p. 26, *op. cit.*, p. 437, *supra*—affirmed that tartar emetic diluted with much water excelled ipecacuanha and all other emetics in this disease, and that it is truly wonderful how much yellow and green humor it brings up, and with what relief to the patient; a beneficial sweat follows, and moreover a thorough purgative effect, p. 27. PRINGLE—*loc. cit.*, note ‡, p. 690, *supra*. MACBRIDE—*loc. cit.*, same note. CHRISTIE—*On the nature and causes of dysentery*, The Med. and Phys. Jour., Vol. I, 1799, p. 465—states that at Bombay, if the tongue was foul and nausea and vomiting occurred, "we generally began by giving an antimonial emetic, as a solution of four or five grains of the antimonium tartarisatum, dissolved in four ounces of water; and the patient directed to take an ounce of this every fifteen minutes till he vomited; and if, as generally happened, it also operated by stool, so much the better." FOURNIER et VAIDY—p. 374, *op. cit.*, p. 362, *supra*—after twenty years' experience, regarded tartar emetic and ipecacuanha as equally suitable in the early stages of simple dysentery: where purgation as well as emesis is desired, the former is preferable; when the flux is already considerable, the latter. A similar view was held by VIGNES—p. 270, *op. cit.*, p. 682, *supra*. VOGT—S. 176, *op. cit.*, p. 645, *supra*—as late as 1856 expressed the opinion that the condemnation of tartar emetic has been carried too far, and advised its use after the method of RASORI, to the extent of 5 to 6 grs. in the twenty-four hours, so as to provoke first vomiting, then purging, and finally diaphoresis in cases accompanied by severe fever, &c.

‡ According to BARBIER, an "emetico-cathartic" should be prepared by combining half a dose of emetic with half a dose of purgative, *e. g.*, one or two grains of tartar emetic with one or two drachms of sulphate of soda or sulphate of magnesia, dissolved in four cups of water; I cite from J. B. BECK—*Lectures on Materia Medica and Therapeutics*, 3d Ed., New York, 1861, p. 32.

§ GILBERT BLANE—p. 455, *op. cit.*, p. 637, *supra:* "It is in all cases of the utmost consequence to administer as early as possible a brisk saline purgative. An ounce and a half or two ounces of purging salts may be dissolved in a quart of barley-water or water gruel, and given warm in cupfuls, at small intervals, till a free and copious evacuation is produced. If there should be much fever, or sickness at stomach, two grains of emetic tartar will be a great improvement of this medicine." A. GRANT—*Fragments of the medical practice in Calcutta at the close of the last century*, The Indian Annals of Med. Science, Vol. VII, 1861, p. 562—tells us that "the practice of commencing the treatment with a dose of Glauber's salts and tartar emetic" was the ordinary routine in the Calcutta hospitals in 1797. R. W. BAMPFIELD—p. 116, *op. cit.*, p. 682, *supra*—commends either sulphate of magnesia or sulphate of soda thus combined. G. B. WOOD—*A Treatise on the Practice of Medicine*, Philada., 1847, Vol. I, p. 572—speaking of the purgatives suitable for dysentery: "Some prefer the neutral salts, as sulphate of magnesia, sulphate of soda, tartrate of potassa and soda, &c. These are especially applicable when there is much fever, with a hot dry skin In such cases, they are sometimes associated with tartar emetic in solution, and given in divided doses, so as at once to relax the skin and operate on the bowels." C. S. TRIPLER and G. C. BLACKMAN—*Hand-book for the Military Surgeon*, Cincinnati, 1861, p. 33: "When a man is attacked with any of the forms of camp dysentery, my constant practice is to give at once a purgative dose of sulphate of magnesia ℥i combined with ¼ to ½ a grain of tartar emetic. If this does not procure copious catharsis, I repeat the dose the next day or the day after. My object is to unload the portal vessels, as well as to remove any irritating matters that may be present in the intestinal canal." TRIPLER has been erroneously credited with originating this practice.

‖ With regard to the anatomical lesions observed after antimonial poisoning, see F. W. BÖCKER—*Die Vergiftungen in forensischer und klinischer Beziehung*, Iserlohn, 1857, S. 36; A. S. TAYLOR—*On poisoning by tartarized antimony*, Guy's Hospital Reports, 3d series, Vol. III, London, 1857 p. 369 *et seq.*—who has collected and tabulated a number of fatal cases, in several of which the post-mortem appearances are recorded. Among the text-books, see WHARTON & STILLÉ—Vol. II, Part 1, p. 441, *op. cit.*, p. 627, *supra;* A. TARDIEU—*Étude Méd.-Légale et Clinique sur L'Empoisonnement*, 2me Éd., Paris, 1875, p. 729 *et seq.;* A. S. TAYLOR—p. 461, *op. cit.*, p. 627, *supra;* and H. C. WOOD—p. 148, *op. cit.*, p. 675, *supra*. For the post-mortem appearances in animals after antimonial poisoning, see C. HANDFIELD JONES—*Exam. of the effects produced by certain medicines. Antimony*, Med. Times and Gaz., N. S., Vol. IV, 1852, p. 362; B. W. RICHARDSON—*Half-yearly report on forensic medicine and toxicology*, British and Foreign Med.-Chir. Review, Vol. XVIII, 1856, p. 521; and NEVINS—*Slow poisoning by antimony*, Pharmaceutical Jour. and Trans., Vol. XVI, 1856–7, p. 415. I may add a significant passage, written by TROUSSEAU—Art. *Antimoine*, Dict. de Méd., 2me Éd., T. III, Paris, 1833, p. 253—at a time when the free use of antimony in medicine was still common: "The traces which tartar emetic leaves in man [after death] have never been determined except when this poisonous agent has been administered as a medicine to patients who have succumbed. An inflammation of the stomach and of the intestine is the only thing that has been found. I have seen in the stomach quite large ulcers and a trifling hæmorrhage."

The use of *ipecacuanha* in the fluxes was made known by Piso (1648) in his De Medicina Brasiliensi. In the extravagant language of his times he described it as a sacred anchor, and as the most exquisite gift of nature. He claimed that it not only evacuated the morbid humors by purging as well as by vomiting, and produced revulsion from the diseased intestine, but that a certain astringent effect succeeded its primary action. He gave at a dose two drachms of the root in infusion or decoction, and repeated this draught next day and even the day following. He describes as the favorite method of administering the drug in Brazil what was afterwards known in France as the Brazilian method, (*l'ipeca à la brésilienne.*) The drug is macerated in water over night, and the infusion administered to the patient; the residue is then macerated again, and the second infusion also administered; this second infusion is less active in its emetic and purgative effects, but more astringent, and serves therefore to restore tone to the viscera.*

But neither the work of Piso nor the importation of a considerable quantity of the root into France in 1672† appears to have received much notice at the time. It was not until after the drug had been used by Adrien Helvetius as an antidysenteric nostrum, and Louis XIV had paid him a thousand louis-d'or to make his secret known, that it attracted general attention from the medical profession. Helvetius was loaded with honors, and ipecacuanha, in spite of a few incredulous doubters, was regarded for a while as a specific for dysentery.‡ As such it was lauded by Baglivi,§ who affirmed that it was an almost infallible remedy for dysenteric fluxes. This reputation it continued to enjoy for a while, and acquired the title of radix antidysenterica, although it was often used injudiciously and several roots of inferior nature were sold under its name.‖

---

* GULIELMUS PISO—*De Med. Brasiliensi*, in Historia Naturalis Brasiliæ, Leyden, 1648, Lib. II, Cap. 11, p. 28: "Dehinc ad radicem Ipecacuanha, tanquam ad sacram anchoram, confugiendum, qua nullum præstantius aut tutius, cum in hoc, tum in plerisque aliis, cum vel sine sanguine, fluxibus compescendis, natura excogitavit remedium. Quippe præterquam quod tuto et efficaciter tenacissimos quosque humores per ipsam alvum, sæpissime autem per vomitum ejiciat, et a parte affecta derivet, vim quoque astrictivam post se relinquit." As to the dose he remarks: "Drugmæ duæ Radicis Ipecacuanha in 3iiij. vini coctæ, vel per noctem maceratæ, cujus infusum cum vel sine oxymelis 3j. exhibetur. Postridie semel atque iterum pro re nata, secunda imo tertia ejus decoctio repetenda, tam quod ægri debiliores eam facilius ferant; quam quod astrictoria ejus vis tunc magis efficax appareat." In Cap. 14, p. 39, he speaks of it as "radicem Ipecacuanha, exquisitissimum naturæ munus," and in Lib. IV, Cap. 65, p. 101, remarks: "Præter facultatem purgatricem per superiora et inferiora, omni veneno eximie adversantur." In the same chapter, after describing the two varieties of ipecacuanha known to him, he gives the method of administering successive infusions as follows: "Utriusque quotidianus est usus, malunt tamen dilutum, quod vel unius noctis sub dio maceratione aut actione in aqua, medicam suam virtutem abunde liquoribus communicet. Postea caput mortuum reservatum, denuoque eodem modo præparatum, in eumdem usum exhibetur; minus quidem efficax ad purgandum vel vomendum, sed magis adstringens. Ita ut radix hæc non solum materiam morbificam, licet tenacissimam, a parte affecta revellat, eamque per superiora expellat, sed et astringendo viscerum tonum restituat."

† It was imported by a physician named LE GRAS: see ELOY—*Dict. Hist. de la Méd.*, Paris, 1755, T. II, p. 26.

‡ ELOY—*loc. cit.*; DEZEIMERIS—*Dict. Hist. de la Méd.*, Paris, T. III, 1836, p. 104; SPRENGEL—Bd. IV, S. 542, *op. cit.*, p. 346, *supra;* MÉRAT—Art. *Ipécacuanha*, Dict. des Sci. Méd., T. XXVI, Paris, 1818, p. 1 *et seq.* It would appear that HELVETIUS, while a student of medicine in Paris, visited, along with AFORTI, a celebrated physician of the faculty and botanist royal, a rich druggist named GRENIER or GARNIER, who on recovery presented to his physicians five or six pounds of the Brazilian root. AFORTI attached no importance to the present, and turned it over to his lucky assistant. HELVETIUS tried it with success, and contrived to import fresh quantities from time to time through GARNIER. The new remedy speedily acquired great renown in his hands, but he kept its nature secret. The cure of several courtiers and finally of the Dauphin, son of LOUIS XIV, raised the fame of HELVETIUS to the highest pitch, and brought about the purchase of the secret by the King. Vainly did the druggist, GARNIER, protest that the credit of the remedy belonged to him. HELVETIUS was appointed esquire, counsellor, medical inspector general of the hospitals of French Flanders, &c. He published, on the use of ipecacuanha in dysentery, a work—*Remède contre le cours de ventre*, Paris, 1688—which I have not been able to see, in which he fixes the dose at two drachms, given in decoction either by the mouth or as a clyster. Sir HANS SLOANE and the celebrated LEIBNITZ assisted by their praises in drawing general attention to the new drug. Among those who attacked the position of HELVETIUS, J. B. ALLIOT—*Traité du Cancer, etc., avec un examen du système et de la pratique de M. Helvetius*, Paris, 1698—appears to have been the chief. In this little tract he chiefly attacks the views of HELVETIUS as to the treatment of cancer; but in the preface he alludes to the remedy for dysentery, the credit for which he claims belongs to GRENIER, and compares HELVETIUS to the jackdaw that borrowed the peacock's feathers. See, also, among the early laudations of the specific virtues of ipecacuanha, the paper of EMANUEL KÖNIG—*Novæ radicis exoticæ, Hipepocoanna dictæ virtus antidysenterica*, Ephem. Med.-Phys. German., Dec. II, An. X, 1691, Obs. 115, p. 209. On the other hand, according to MÉRAT—p. 28, *op. cit.*, *supra*—TOURNEFORT observed that the remedy did not answer so well in camp dysentery as in the sporadic cases, and GEOFFROY observed that it was less efficacious among the squalid poor than among the more comfortable classes; which is readily understood if we consider the greater frequency of severe diphtheritic cases in camps and among the poor.

§ BAGLIVI—*Prax. Med.*, Lyons, 1699, Lib. I, Cap. 9, p. 79: "Radix hipecacuanhæ est specificum, ac ferme infallibile remedium in fluxibus dyssentericis, aliisque hæmorrhagiis sanguineis, colliquationibus humorum," &c. In support of this statement he cites the testimony of the English physician and botanist, WM. SHERARD, and that of the celebrated Swiss physician, J. J. MANGETUS, as well as the work of PISO.

‖ DEGNER—Cap. III, § 14, p. 129, *op. cit.*, p. 625, *supra*—remarks: "Nonnulli radicem illam e Brasilia allatam, ipecacuanham dictam, tanquam primarium et specificum contra dysenterias emeticum commendant, quia cum in India Orientali, tum in Occidentali, in omnibus dysenteriis et diarrhœis magno cum successu adhibetur, unde etiam nomen radicis antidysentericæ κατ' ἐξοχὴν accepit." JAMES—Vol. II, *op. cit.*, p. 690, *supra*, Art. *Ipecacuanha*—gives as a reason for the failure of some of those who tried it that it was given in the quantity of two drachms at a dose, which was too great. Yet this was the dose that PISO—Lib. IV, Cap. 65, p. 102, *op. cit.*, note *, *supra*—used in decoction of the brown or more active ipecacuanha; in powder

Degner, who employed it with success in the Nimeguen epidemic, shrewdly pointed out that its usefulness is limited to the early stages of the disease, before organic lesions of the intestinal tissues have actually occurred. He held that at this period it not merely acts in the modes described by Piso, but that it has peculiar and specific virtues possessed by no other drug. He gave the powder in the dose of half a drachm to two scruples, repeated a second or even a third time if the disease did not yield.* The belief in the specific powers of ipecacuanha gradually died out; Hoffmann held that it owed its value merely to its evacuant action, that it was not always necessary, nay, even that it often produced injurious effects;† but even those who took this view of its operation preferred it to other drugs of the same class. It is recommended as an emetic in the early stages of dysentery by Van Swieten, Tissot, Akenside, Hillary, Zimmermann, Geach and Moseley;‡ while Pringle, Macbride and Donald Monro§ gave it under the same circumstances combined with a little tartar emetic to increase the activity of its operation.

Exaggerated notions of the beneficial action of emetics, the result of the former belief in the specific powers of antimony and ipecacuanha, undoubtedly led to extravagances in their use, and the consequent disasters brought about a reaction in medical opinion on this subject. Cullen not merely denied the specific powers of ipecacuanha, but asserted that no emetic can be of much service unless it operates also by stool, and cautioned against repeating the administration of such medicines too frequently.‖ Hunter advised that purgatives should be preferred, pointing out that the sickness produced by an emetic is always distress-

---

he states its dose to be a drachm. SPRENGEL—*loc. cit.*, note ‡, last page—appears erroneously to suppose LEIBNITZ to have been the first to mention the use of the drug in powder. Besides the brown, PISO—*op. cit.*, p. 101—described a milder variety under the title ipecacuanha blanca. J. DOUGLAS, in the Philosophical Transactions—I cite JAMES, *loc. cit.*—was acquainted with "four kinds, black, brown, grey, and white," but was unable "to determine whether they belong to different plants, or are only varieties of the same plant, owing to the soil in which they grow, as is affirmed by Sir Hans Sloane." WALTER HARRIS—*Diss. Med. et Chir.*, London, 1725, p. 250; I quote from SPRENGEL, *loc. cit.*—states that the English apothecaries sometimes sold a poisonous root under the name of ipecacuanha.

* DEGNER—paragraphs following *loc. cit.*, last note: "Sed etiam eadem ipecacuanha in nostra dysenteria mirabiles effectus edidit," § 20, p. 134. "Conducit autem hæc radix in omnibus casibus, ubi causa morbosa adhuc in primis viis hæret mobilis, et, quod notandum, partes solidas nondum adfecit," § 16, p. 131. "Nam præter effectum suum emeticum simul adeo *peculiare* et *specificum quid* operatur, ut alia vomitoria eam non facile æquent," § 17, p. 132. He points out that if after its use the flux increases and the strength of the patient fails, the prognosis becomes unfavorable, § 27, p. 138.

† HOFFMANN—T. III, p. 155, *op. cit.*, p. 681, *supra*. He gave from a scruple to half a drachm, followed by large draughts of tepid water to promote vomiting. In a subsequent passage—Cautelæ, § 6, p. 157: "Radix ipecacuanhæ, quæ pro specifico antidysenterico a multis habetur, non omnino suo caret usu; licet etiam sæpissime sinistros producat effectus." He regarded it as most likely to be useful in robust subjects when the primæ viæ were loaded with crude materials, or the patient had recently been exposed to a contagious miasm.

‡ VAN SWIETEN—*loc. cit.*, p. 690, *supra*. TISSOT—T. III, p. 8, *op. cit.*, p. 625, *supra*—who wrote: "Le grand remède de cette maladie, c'est l'émétique." He used for this purpose either his "remède No. 24," which was 6 grains of tartar emetic, or his "remède No. 35," which was 35 grains of ipecacuanha, and appears to have regarded them about equally useful. Of the latter he remarks: "Il avoit même été regardé très-longtems comme un spécifique sûr: il ne l'est pas, mais il est très-utile." AKENSIDE—p. 34, *op. cit.*, p. 681, *supra*—administered a scruple of ipecacuanha at the beginning of the disease after bleeding. "ut omni inutili onere ventriculus levetur." HILLARY—p. 209, *op. cit.*, p. 681, *supra*—followed the same plan, but if this failed to give relief resorted to the cerated glass of antimony. I may add that CLEGHORN—Chap. 5, p. 249, *op. cit.*, p. 637, *supra*—used these two emetics almost indifferently, though he remarks: "I prefer the ipecacuanha, as being certain in its operation; whereas the other sometimes did not produce the intended discharge, at other times occasioned greater commotions than were expected." ZIMMERMANN—Cap. 5, S. 80, *op. cit.*, p. 648, *supra*—in the Swiss epidemic began the treatment with an emetic of ipecacuanha, giving at the most 40 grains. He gave it with good results, even when not sent for till a week or two after the beginning of the disease, unless he suspected ulceration or suppuration of the bowels—S. 82; yet in a subsequent part of this work, in connection with a scholastic picture of inflammatory dysentery, he declares that in this variety of the disease emetics are a deadly poison—"ein tödendes Gift,"—S. 382. GEACH—p. 21, *op. cit.*, p. 669, *supra*. MOSELEY—p. 229 *et seq.*, *op. cit.*, p. 648, *supra*.

§ PRINGLE—*loc. cit.*, note ‡, p. 690, *supra*. MACBRIDE—*loc. cit.*, p. 664, *supra*. DONALD MONRO—p. 70, *op. cit.*, p. 625, *supra*. I may mention here that A. STILLÉ—*Therapeutics and Materia Medica*, 4th Ed., Philada., 1874, Vol. II, p. 450—has fallen into a curious mistake as to PRINGLE'S views with regard to ipecacuanha, remarking: "He, indeed, laid it aside on account of the distress produced by its action; yet he adds, 'Upon the whole, I am not clear whether it is not the surest method of cure.'" The passage cited occurs only in the first three editions of the *Diseases of the Army;* and an examination of these will show that it relates to the plan of giving five grains of ipecacuanha at a time, "repeated twice or thrice in the same day, till a vomiting or purging came on," instead of giving a single dose. Of this plan PRINGLE says: "I laid it aside on account of the excessive sickness that generally accompanied the operation; tho' upon the whole I am not yet clear, whether it is not the surest method of cure," 1st Ed., London, 1752, pp. 277–8. In the 3d Ed., London, 1761, pp. 237–8, the passage is modified so as to read, instead of "I laid it aside," "yet I did not always use it, on account of," &c. In the 4th Ed., London, 1764, p. 271, this passage is omitted, and the practice of giving a scruple of ipecacuanha is recommended, with the addition of two grains of tartar emetic, "for the common men," or five-grain doses may be given, "repeated at an hour's distance, twice or thrice, till a purging was brought on." Nothing is said any more of the excessive sickness. In the 7th Ed., London, 1774, p. 261, the same practice is commended, except that the tartar emetic is no longer reserved for the common men, but is now said to be "generally added."

‖ CULLEN—*First Lines*, § 1081, Vol. II, p. 325, Ed. cited p. 648, *supra:* "Vomiting has been held a principal remedy in this disease; and may be usefully employed in the beginning of it, with a view to both the state of the stomach and of the fever: But it is not necessary to repeat it often; and unless the emetics employed operate also by stool, they are of little service. Ipecacuanha seems to possess no specific power; and it proves only useful when so managed as to operate chiefly by stool."

ing and that it is most beneficial when it also purges.* Even Max. Stoll, who so zealously advocated the use of emeto-cathartics at the commencement of bilious dysentery, taught that, if imprudently reiterated, emetics exhaust the vital powers, render the disease more obstinate, and that when the dysentery is accompanied by a putrid fever an emeto-cathartic is not well borne because of the prostration that follows its use.† Fournier and Vaidy forbade emetics in the so called inflammatory dysentery, insisting that they could only serve to irritate the already inflamed mucous membrane.‡

The use of emetics now fell into pretty general disfavor. This was due in part to the popularity acquired by purgative medicines, especially calomel,§ in part to the influence of Broussais, who asserted that emetic doses of ipecacuanha often act injuriously upon the colon, rendering the flux bloody and painful instead of curing it; advised that their use should be restricted to special cases, and altogether denied that ipecacuanha possesses any antidysenteric virtues.‖ Baly's experience with ipecacuanha was equally unfavorable.¶ Bamberger, while he admitted that emetics may occasionally prove serviceable at the beginning of the disease, by evacuating the stomach if it be loaded with undigested food, held their employment for any other purpose to be purely empirical and likely to do more harm than good; he favored the use of small doses of ipecacuanha for its diaphoretic action, especially in the milder cases, but, even thus administered, thought the resulting benefit was in great part to be ascribed to the opium with which it is usually combined.**

Even during this period of neglect, however, there were a few physicians who continued to treat dysentery with ipecacuanha in large doses. Balmain was induced by his knowledge of the success of an empiric to give two drachms of the powder at a dose, with the addition of sixty drops of laudanum, during an epidemic at Norfolk Island in the spring of 1795. He found that, if the patient was kept still, nausea seldom followed, and oftentimes he had no stool at all next day, although previously the gripings had been violent and the bloody discharges frequent.†† Playfair,‡‡ while surgeon of an Indiaman in 1803–4,

* J. HUNTER—p. 238, *op. cit.*, p. 637, *supra.*

† MAX. STOLL—T. III, p. 259, *op. cit.*, p. 342, *supra*—especially commends the use of the emeto-cathartics in the variety of dysentery which he calls *rheumatico-biliosa.* He treated all the dysenteries of the summer of 1776, and many of the cases he saw in Hungary in 1773–4, in this manner. For the objections and limitations to their use referred to in the text, see pp. 267–8.

‡ FOURNIER et VAIDY—p. 392, *op. cit.*, p. 362, *supra*—did not hesitate, however, even in these cases to give small doses of tartar emetic for its diaphoretic action. They used larger doses of the same drug, or ipecacuanha, as emetic in simple and mucous dysentery, pp. 374 and 394, and even at the beginning of the disease in dysentery complicated with typhus, p. 396, and adynamic dysentery, p. 398.

§ See, *infra*, the remarks on the general use of calomel as a purgative in dysentery during the early part of the present century.

‖ BROUSSAIS—T. III, p. 227 *et seq.*, *op. cit.*, p. 643, *supra:* "Je ne lui reconnais aucune vertu anti-dysentérique." He declares that he made use of ipecacuanha for a long time, and if in six cases it diminished the flux, which might have been done better by other means, it aggravated it in the seventh, producing a decided condition of inflammation which had subsequently to be combated. He therefore limited its use to cases where the stomach contained worms or where it seemed probable that there was an accumulation of bile in the stomach or liver.

¶ BALY—p. 536, *op. cit.*, p. 535, *supra:* "But ipecacuanha has wholly failed in my hands as a specific, or in any way active, remedy for the disease."

** BAMBERGER—S. 415–416, *op. cit.*, p. 578, *supra.* NIEMEYER—Bd. II, S. 755, *op. cit.*, p. 645, *supra*—also limits its use to the beginning of the disease and to cases in which the stomach is filled with undigested food. On the other hand, TROUSSEAU—T. III, p. 170, *op. cit.*, p. 664, *supra*—although he prescribed ipecacuanha only at the beginning of the disease and in emetic doses, believed it to act as a powerful modifier, much like the purgatives, on the whole digestive tube as well as the stomach. He regarded it as most useful in bilious dysentery.

†† W. BALMAIN—*An account of the effects of ipecacuanha in the cure of dysentery at Norfolk Island*, Memoirs of the Medical Society of London, Vol. V, 1799, p. 210. He made the powder into pills, "which were made as large as possible to admit of their being swallowed." The patient "lay on his back, with the head and chest tolerably elevated." A dose of Glauber's salts was generally administered before the ipecacuanha, and thought to render it more efficacious.

‡‡ GEORGE PLAYFAIR—*On the good effects of a combination of ipecacuan and laudanum in dysentery*, The Edinburgh Med. and Surg. Jour., Vol. IX, 1813, p. 18—was undoubtedly induced to try this plan by the success of BALMAIN, for he writes: "I recollected to have seen in, I think, a medical review, that ipecacuan and opium had been tried in large doses with effect. The hint determined me to make the experiment, and I had every reason to be grateful for the success with which it was attended. * * * I prescribed from half a drachm to a drachm of ipecacuan, combined with from 30 to 60 drops of laudanum, confining the patient for some hours afterwards to a horizontal posture. It often happened, however, that notwithstanding their attention to remain in this position, the first dose was vomited, but a second was commonly retained. It was usually the case, that after the medicine was taken, no inclination to stool was experienced for many hours, the patient being, during that time, easy and free from the griping pain; several loose motions then took place, but unmixed with blood, and unattended with tenesmus. * * * Seldom more than one dose was required to cure the disease; but when any symptoms remained, a repetition next day was sufficient to produce the desired effect. It must however be remarked, that this treatment was always adopted at the commencement of the attack; for when the disease had been of any standing, the stomach was too irritable to retain the medicine even for an instant. Its good effects certainly did not follow a relaxation of the surface of the body; such a circumstance seldom occurred."

adopted the same practice with equally favorable results. Smaller non-emetic doses of ipecacuanha were strongly recommended by Twining in 1829.* Emetic doses were regarded as occasionally useful by Vignes, and Hauff reports that they were freely prescribed by several of the Wurtemberg physicians during the epidemic of 1834.†

Ségond in 1835 drew attention anew to the Brazilian method of successive infusions, which, however, he employed chiefly in what he called the serous variety of dysentery. He made and administered a third infusion from the same dose of the drug, while Piso described but two.‡ This modified method appears to have enjoyed considerable popularity among the French naval surgeons in the treatment of tropical dysentery.§ In 1851 it was made the subject of a special essay by Savignac. In his experience the first infusion almost always provoked vomiting, and sometimes, but not always, numerous stools; the second infusion, given next day, seldom vomited, the stools continued of about the same frequency or diminished in number; more or less nausea was pretty constantly felt; the third infusion, given on the third day, did not usually nauseate, and the stools now began to diminish in frequency, unless the disease was too violent to yield to the medicine. In the sporadic dysenteries of Europe two or three grammes of ipecacuanha thus given usually sufficed to modify the morbid condition; if it did not, a second or even a third series of infusions was ordered. The beneficial effects of the drug were in his opinion due, not merely to its emetic and purgative action, nor yet to the diaphoresis which almost invariably followed its use, but to a peculiar dynamic sedative and alterative action.‖

This memoir did not at the time attract much notice out of France, but a few years later renewed attention was directed to the use of ipecacuanha in dysentery by the memoir of Docker, (1858,) who had successfully employed it on the island of Mauritius. His method of administration was essentially similar to that of Balmain and Playfair. The patient was put to bed, a draught containing a drachm of laudanum administered and a sinapism applied over the stomach; half an hour later a dose of ipecacuanha, usually from twenty to thirty grains, but sometimes as much as a drachm or a drachm and a half, was administered. In many cases this dose was not followed by emesis, but if it was he repeated it at once until it was retained, except in the case of the larger doses, when he generally

* TWINING—*Obs. on the employment of large doses of ipecacuanha in dysentery, without exciting vomiting*, Trans. of the Med. and Phys. Society of Calcutta, Vol. IV, 1829, p. 174—regarded six grains as a large dose. He gave it every night at bed time, combined with four grains of extract of gentian and five of blue mass. The latter ingredient was omitted after "a cessation of all the distressing symptoms" was obtained.

† VIGNES—*loc. cit.*, p. 682, *supra*. He prescribed it if there was gastric embarrassment at the beginning of the disease, with thin or copious stools. Under the same circumstances, if the stools were scanty and the patient strong, he preferred tartar emetic. If he gave ipecacuanha, the dose was half a drachm or more, given in hot infusion. HAUFF—S. 401, *op. cit.*, p. 534, *supra*—recommends mere emetic doses in all forms of dysentery except the inflammatory. Their use by the Wurtemberg physicians is also mentioned on S. 111, 120, &c.

‡ SÉGOND—*Considérations pratiques sur la nature et le traitement de la dysenterie*, Jour. Hebd., T. I, 8me Année, 1835, p. 175 *et seq.*—made three varieties of dysentery, the sanguine, the bilious and the serous, and recommended *l'ipéca à la brésilienne* chiefly in the latter. He used, to make the infusions, 24 grains of the drug. It would appear from his remarks that this method was not infrequently used by his contemporaries, for he remarks: "Tout médecin qui administre l'ipéca d'après cette formule, évite soigneusement que la plus petite quantité de marc ne se mêle à l'infusion; mais ce marc, dira-t-on, étant parfaitement inerte, après trois infusions et macérations de la substance mère, cette crainte est chimérique." FABRE—*Traité de matière médicale et de thérapeutique*, in Bibl. du Méd. Praticien, T. XIV, Paris, 1850, p. 404—also described the method of making three successive infusions. He used 8 grammes of the drug and 120 grammes of water for each infusion.

§ SAVIGNAC—p. 100, *op. cit.*, next note: "If a great number of physicians on the Continent are ignorant of this method or neglect to use it, there is perhaps not a single naval surgeon, who has observed and treated dysentery in the tropical colonies, who does not know it, who has not seen others use it or used it himself."

‖ J. DELIOUX DE SAVIGNAC—*Mémoire sur l'ipéca*, (lu à l'Acad. Nat. de Méd., Juin 3, 1851,) Gaz. Méd. de Paris, T. VII, 1852, p. 87 *et seq.*—equally lauds the virtues of ipecacuanha given in the Brazilian method in the treatment of pleuro-pneumonia. When this method is used in dysentery, tolerance is soon established, the abdominal pains diminish; the stools diminish in frequency and become more healthy in appearance; the pulse becomes slower and the fever diminishes, and a slight but sufficient diaphoresis occurs. As to its mode of action, he writes: "Pour moi, l'ipéca est un hyposthénisant pur, un sédatif (ce dernier terme est plus intelligible et exclut mieux tout préjugé doctrinal), un sédatif portant particulièrement sur les systèmes nerveux et sanguin; un altérant aussi, peut-être, qui introduit dans nos humeurs l'un de ces principes qui, à si petites doses, suscitent des effets si intenses dans l'organisme," p. 104. This memoir was referred to a committee, MM. GUIBOURT, PÂTISSIER and DESPORTES, who, in their report, while recommending that the studious zeal of the author should be encouraged by thanks for the communication of his work, were cautious not to commit themselves to his speculations as to the action of the drug—Bull. de l'Acad. Nat. de Méd., T. XVI, 1850–1, p. 1231. F. LAURE—*Hist. Méd. de la Marine Française pendant les Expéditions de Chine et de Cochinchine*, Paris, 1864, p. 52—relates that this precious agent rendered great service in the French expedition to China.

waited ten or twelve hours before repeating. A single dose, however, often sufficed for a cure; the pains promptly subsided and the stools ceased. He gave it to patients of various constitutions, and in all stages of the disease, with equal benefit; and out of upwards of fifty cases lost but one. As to the mode in which the drug acted he offered no theory, but expressed his belief that the time would come when it would be regarded as much a specific in dysentery "as bark is in ague and sulphur in itch."*

The rapid and successful introduction of Docker's method in India is sketched in the papers of Donaldson, Massey, Cornish, Cunningham and Ewart.† There were not wanting some who, like Blacklock, cautioned against its indiscriminate use, and declared that in unsuitable cases, when the local disease is too far advanced, or the patient in an asthenic condition, it aggravated instead of mitigating the disease.‡ But such warnings seemed to secure little consideration; its indiscriminate administration became pretty general in India, and Docker's method was soon introduced into England, where it received the support of Waring, Maclean and Aitken.§ These writers commend it chiefly in acute cases, but it appears from various journal articles‖ that it has also been pretty freely used in the chronic

* E. S. DOCKER—*On the treatment of dysentery by the administration of large doses of ipecacuanha*, The Lancet, 1858, Vol. II, pp. 113 and 169: "The ipecacuan is administered—generally in a draught, sometimes in the form of pill or bolus—and the semi-recumbent posture steadily maintained." As to its effects he says: "In all constitutions, robust as well as delicate, under all circumstances, the result is the same. In the very worst cases, when the strength of the patient is almost exhausted, after the whole range of remedies has been tried in vain, the disease running its course swiftly and surely to a fatal issue, ninety grains of ipecacuan have been given, and forthwith the character of the disease, or, I should rather say, the character of the symptoms has been entirely changed; for the disease itself is literally cured, put a summary stop to, driven out." He gives, in illustration of the mode in which the drug acts, a sketch of five successfully treated cases and one fatal case. Towards the close of this paper he remarks: "As regards the rationale of the action of ipecacuan in large doses, I will not venture on so debateable a point to express an opinion. That it is a very energetic *tonic* is sufficiently evident; equally certain that it is a most powerful *styptic*, (this being the effect of its tonic property)," &c.

† JAMES DONALDSON—*On the diarrhœa and dysentery of India and China*, Edinburgh Med. Jour., Vol. V, 1859-60, p. 583—reports that DOCKER'S method (he writes, "I am sorry I have forgotten his name") was "introduced into Madras, or rather recommended for adoption in India, by Dr. M. Rogers." He himself tried it in doses of 30 grains, and was "much gratified with the perfectly successful result," p. 589. He reports 8 successful cases. MASSEY—*On acute dysentery, referring especially to its treatment by large doses of ipecacuanha in the regimental hospital of the 2nd dragoon guards during the year 1859, in Oude*, Statistical, Sanitary and Medical Reports, (British Army,) for the year 1859, p. 280. W. R. CORNISH—*Remarks on the treatment of acute tropical dysentery by large doses of ipecacuanha*, &c., The Madras Quarterly Journal of Med. Science, Vol. II, 1861, p. 41—gives a further account of the introduction of this method in India. He shows that from 1842 to 1859 the mortality from dysentery among the European troops in the Madras army had averaged 7.1 per cent. of the cases treated; while of 297 cases among the same troops treated after 1858 with ipecacuanha, only 4, or 1.3 per cent., had died. R. W. CUNNINGHAM—*On the treatment of acute dysentery by ipecacuanha*, Edinburgh Med. Jour., Vol. VII, 1861, p. 25—writes that the plan of Surgeon DOCKER is rapidly superseding all other modes of treating dysentery in India. J. EWART—p. 378 *et seq.*, *op. cit.*, p. 681, *supra*—gives an interesting account of the progress of this method in Bengal, Madras and Bombay up to 1862. He tabulates, in addition to the cases of CORNISH in Madras, 658 cases of Europeans thus treated in Bengal, with a mortality of 19, or 28.87 per 1,000—p. 392; and estimates the diminished mortality, resulting from the introduction of the ipecacuanha treatment, at 46.63 per 1,000 cases treated—p. 394. As to its mode of action, he remarks: "Thus, it may be said that we possess, in ipecacuanha, a direct and safe antiphlegistic, a powerful sudorific, an unirritating purgative, a certain cholegogue, a pancreatic stimulant, and a harmless sedative to the heart and muscular fibres of the large intestine,"—p. 403.

‡ A. BLACKLOCK—*Report on cases of acute dysentery treated by large doses of ipecacuanha*, The Madras Quart. Jour. of Med. Science, Vol. II, 1861, p. 256 *et seq.*: "When I first arrived in India, I saw cases successfully treated by large doses of ipecacuanha; but I also saw others in which ipecacuanha aggravated instead of mitigating the disease. I now regard these failures as cases of ipecacuanha dysentery,"—p. 292. The great danger of the large-dose method, he says, is, "that the power of the heart may become so much impaired by its continuance, that the brain may soon be too sparingly supplied with blood, and general unmanageable prostration ensue, while at the same time the local congestion increases with the debility. * * * Like tartar emetic, and all other evacuants, ipecacuanha induces, when continued too long, the very state of vessels we find in inflammation,"—p. 290. He regards it as a remedy of great value in sthenic dysentery, to which it should be restricted. Here, too, I may refer to the cautious paper of H. CLARK—*On the use of ipecacuanha in dysentery*, The Indian Annals of Med. Science, Vol. VII, 1861, p. 553—who remarks that his own experience, "while it exhibits the favorable action of the ipecacuanha clearly enough, is, I think, inconsistent with the idea of its acting as a specific in dysentery," p. 557; and declares that he "should be sorry to rush to the conclusion that ipecacuanha is a medicine universally eligible in acute dysentery," p. 560. I may add that MOREHEAD—p. 298, *op. cit.*, p. 657, *supra*—while commending the use of ipecacuanha in dysentery, attributing its virtues, as PRINGLE did, to its "laxative or purgative effect," was by no means convinced of the justness of DOCKER'S enthusiastic views, remarking: "I regret this returning cycle of indiscriminate use and praise which is sure to lead to injurious reaction." On the other hand, however, Sir JAMES RANALD MARTIN—p. 461 *et seq.*, *op cit.*, p. 621, *supra*—has pretty fully endorsed the correctness of DOCKER'S views, and points out that he himself suggested the propriety of giving large doses of ipecacuanha in dysentery as early as 1837.

§ E. J. WARING—*Practical Therapeutics*, American reprint of the 2d Ed., Philada., 1866, p. 389. W. C. MACLEAN—p. 121, *op. cit.*, p. 657, *supra*: "Under the old system in Bengal the mortality among Europeans during the forty-two years, from 1812 to 1853-54, amounted to 88.2 in the thousand." In contrast to this he cites the figures of CORNISH and EWART, see note †, *supra*. He remarks: "It is probable that ipecacuanha owes much of its usefulness in this disease to its action as an evacuant. It is a blood depurant of an effective kind. It appears to increase the secretion of the whole alimentary canal, as well as that of the liver and pancreas; under its use tormina and tenesmus disappear, and feculent evacuations are more quickly restored than by any other known remedy. It also promotes free action of the skin, and exercises a sedative action on the circulation." "If unmanageable vomiting follows the use of ipecacuanha, hepatic complication of a serious kind may be suspected—or the vomiting may arise from the system being overcharged with malaria." AITKEN—p. 658, *op. cit.*, p. 647, *supra*.

‖ Among these I may note M'KIDD—*On the therapeutic effects of ipecacuanha in diarrhœa and dysentery*, Edinburgh Med. Jour., Vol. VII, 1861, p. 86—reports a case of chronic diarrhœa, cured, to the Med.-Chir. Society of Edinburgh. Remarks favorable to the use of ipecacuanha in diarrhœa and dysentery were made by W. BEGBIE, SPENCE and P. H. WATSON. WILLSHIRE—*Clinical lecture on a case of chronic dysentery treated with ipecacuanha*, The Lancet, 1862, Vol. II, p. 62. HILLIER—Med. Times and Gazette, 1864, Vol. I, p. 123—is said to have tried DOCKER'S method successfully in a child

forms, in which, however, Ward declares that after a fair trial in the Seamen's hospital he failed to satisfy himself of its efficacy.*

Although the method of Docker had been made known in the United States by several publications,† the use of ipecacuanha in large doses was not very extensively tested during our civil war. A few of the surgeons in the field resorted to it and reported favorable results,‡ but its trial in Eckington hospital, Washington, D. C., on a more serious class of cases, many of them chronic, terminated in disappointment,§ and like results are reported in the epidemic at Columbia, in South Carolina, in 1868.‖ I find, however, in the American medical journals several reports of the successful use of ipecacuanha, on the non-emetic plan, in sporadic cases of acute dysentery,¶ and even in chronic fluxes.** A number of similar cases are also reported in the monograph of Surgeon A. A. Woodhull, U. S. A.††

Meanwhile ipecacuanha has been employed to a certain extent in the treatment of dysentery on the continent of Europe. Its non-emetic administration is said to have had fair success during the late Franco-German war in the English hospital at Metz, as well as

four years old. He gave five minims of laudanum, followed in half an hour by 15 grains of powdered ipecacuanha. No nausea or other unpleasant symptom resulted. DYCE DUCKWORTH—*Obs. upon the action of ipecacuanha and its alkaloid emetia, Part II*, Saint Bartholomew's Hospital Reports, Vol. VII, London, 1871, p. 113—has also expressed the opinion that large doses of ipecacuanha may advantageously be resorted to in cases of chronic colitis. He reports, however, a case in which this treatment, although supplemented with enemata of ipecacuanha, was vainly tried: the patient "left the hospital but little relieved."

* STEPHEN H. WARD—*On the treatment of chronic dysentery*, Med. Times and Gaz., 1873, Vol. I, p. 194. His views are supported by the testimony of the senior resident physician of the same hospital, HARRY LEACH—*Clinical remarks on chronic dysentery*, The Practitioner, Vol. V, 1870, p. 350.

† See, for example, an abstract of DOCKER'S paper in the American reprint of *Braithwaite's Retrospect*, Part XXXVIII, 1859, p. 86; and an abstract of the paper of CORNISH—see note †, last page—published by E. H. JANES—Amer. Med. Times, Vol. III, 1861, p. 28—who expresses the opinion "that ipecacuanha is a valuable remedy in acute uncomplicated dysentery, if given boldly and continued at proper intervals until fæcal evacuations appear." So, too, RICHARD WHITTINGHAM, surgeon Peruvian navy—*On tropical dysentery*, The Amer. Jour. of the Med. Sciences, N. S., Vol. XL, 1860, p. 379—had strongly commended the use of ipecacuanha in large doses, both by the mouth and enema, in common and bilious specific dysentery, as the result of a four years experience in the general hospital at Callao, Peru. He administered by the mouth half a drachm to a drachm of powdered ipecacuanha, "not given as an emetic, but to produce its specific action on the disease." STILLÉ, in his paper circulated by the Sanitary Commission—p. 368, *op. cit.*, p. 650, *supra*—commended the administration of 25–30 grains of ipecacuanha for its emetic effect in the early stages of bilious dysentery, but also described WHITTINGHAM'S method. I may add that, if we can believe a note by A. P. MORRILL—*Ipecacuanha in dysentery*, The Med. and Surg. Reporter, Vol. XXIII, 1870, p. 503—the Brazilian method of successive infusions had previously been in common use in the southern states, [he says 50 years ago, which is probably an error of memory or a misprint for 30 years ago.]

‡ See, in Section II, the reports of BLADES—p. 91, *supra*—and MCELROY—p. 92, *supra*—who used with success large doses of ipecacuanha guarded by opium. I may add that COOPER—p. 93, *supra*—succeeded with frequent purging by castor oil, followed in the intervals by the free use of opium and ipecacuanha; while WALTON—p. 93, *supra*—found a mustard emetic, with or without ipecacuanha, cured half his cases of diarrhœa; and BROWN—p. 81, *supra*—used an emetic of ipecacuanha combined with tartar emetic, "to unload the portal system." See, also, a paper by J. F. HAMMOND—*Brief account of dysentery as it occurred at Fort Jefferson, Tortugas, Florida*, Amer. Jour. of the Med. Sciences, Vol. XLIII, 1862, p. 69—who commends an emetic of ipecacuanha at the beginning of the disease. On the Confederate side, G. S. KING—*Ipecacuanha in dysentery*, The Med. Record, Vol. III, 1868, p. 43—reports that he used DOCKER'S plan with success in a number of cases in the Baptist College hospital, Richmond, Va. He never resorted to it, however, until other means had failed.

§ See, in Section II, the report of STOREOW—p. 43, *supra*—and a paper by Acting Assistant Surgeon HENRY N. FISHER—*Remarks on chronic army diarrhœa*, Amer. Med. Times, Vol. VI, 1863, p. 4.

‖ See, in Section II, the report of COUES—p. 64, *supra*.

¶ The following report the successful treatment of cases of acute dysentery by DOCKER'S method: JOEL C. HALL, Vicksburg, Miss.—*The value of ipecacuanha in the treatment of acute dysentery*, The Med. and Surg. Reporter, Vol. XVIII, 1868, p. 144. DAVID W. YANDELL—*An abstract of a report of some cases of dysentery treated by large doses of ipecac.*, The Western Jour. of Med., Vol. IV, 1869, p. 473—who advises that the ipecacuanha should be guarded by morphia administered hypodermically, instead of by the preliminary dose of laudanum. JOHN STEPHEN—*Ipecacuanha in large doses in acute dysentery*, The Med. and Surg. Reporter, Vol. XXIII, 1870, p. 419. THOS. M. WOODSON—*Treatment of dysentery by large doses of ipecac.*, The American Practitioner, Vol. IX, 1874, p. 31—nine cases, in all but one of which, however, vomiting followed the use of the drug. M. LEWIS—*Clinical record of six cases of dysentery treated with ipecacuanha*, The Amer. Med. Weekly, Vol. III, 1875, p. 205. FOURNIER, READ and ROSS—*Proceedings of the Mobile Med. Society*, Virginia Med. Monthly, (Richmond,) Vol. II, 1875–6, p. 517. J. E. MORRIS—*Dysentery treated with ipecac.*, The New Orleans Med. and Surg. Jour., Vol. III, 1875-6, p. 356; also letter by *Alumnus of the University of La.*, from Danville, Ky., same Vol., p. 443. E. J. FORSTER—*Three cases of dysentery treated successfully by large doses of ipecacuanha given by the non-emetic plan*, Boston Med. and Surg. Jour., Vol. XCVI, 1877, p. 218. Success, with a modified method, is reported by A. A. HŒHLING, U. S. Navy—*Ipecacuanha in dysentery*, The Med. and Surg. Reporter, Vol. XIX, 1868, p. 327—in a case treated at Valparaiso, Chili, by the following mixture: R. Ipecacuanhæ ʒss, Mannæ ʒij, Aquæ bullientis fʒxij. Dose, fʒij, repeated every three hours till one dose was retained, and then suspended. This occurred after the sixth dose, when pills of camphor, ipecacuanha and opium were substituted.

** For reports of cases of chronic fluxes successfully treated with ipecacuanha, see the papers of H. D. BULKLEY—*On the use of ipecacuanha in chronic dysentery and diarrhœa*, Amer. Med. Times, Vol. IV, 1862, p. 64, and *Notes of hospital practice: Chronic dysentery*, The Medical Record, Vol. II, 1867–8, p. 489. His method was to give 10 grains three times a day. JAMES B. BURNET—*Cases of chronic dysentery treated with ipecacuanha*, The (N. Y.) Med. Gaz., Vol. I, 1868, p. 251—reports the successful use of the same method in the service of Prof. A. L. LOOMIS. Asst. Surgeon W. E. WHITEHEAD, U. S. A.—*Treatment of chronic dysentery with large doses of powdered ipecac.*, Pacific Med. and Surg. Jour., Vol. IV, 1870–1, p. 11—used essentially the same method, 8–15 grains three times daily.

†† A. A. WOODHULL—*Studies chiefly clinical in the non-emetic use of ipecacuanha*, &c., Philadelphia, 1876, pp. 1–30—reports 28 cases of acute and chronic diarrhœa and dysentery successfully treated. This monograph is enlarged from a paper by the same author—*Clinical studies with large non-emetic doses of ipecacuanha*—originally published in the Atlanta Med. and Surg. Jour., Vol. XII, 1874–5, pp. 659 and 705, and reprinted in pamphlet form, Atlanta, Georgia, 1875.

in the hands of several of the surgeons of the besieging army.* Heubner approves the use of the drug, though only as an emetic, at the beginning of dysentery; but the plan of Docker has been warmly commended by Brunner.† In France the Brazilian method, as modified by Savignac, continues to be employed,‡ but has been replaced to some extent by the ipecacuanha enemata, which have also recently found much favor elsewhere, as will be related further on in connection with the subject of enemata.

It will be observed, therefore, that in the most modern times the use of ipecacuanha in the treatment of the fluxes has reëstablished the reputation it enjoyed in the seventeenth century, and is regarded in many quarters with a confidence as blind as that reposed in it by Piso or Helvetius. Nevertheless a little reflection must show the absurdity of expecting benefit from such a remedy either in acute diphtheritic dysentery after the formation of the diphtheritic layer, in the chronic fluxes after extensive ulceration has already occurred, or in those cases which owe their virulence to the coexistence of a scorbutic or some other constitutional taint. The value of the detailed clinical records of success or failure, which have been accumulated by the labor of more than two hundred years, is greatly impaired by the circumstance that no serious attempt seems to have been made, since the time of Degner,§ to discriminate the pathological conditions actually existing in the cases in which the drug has been tried; but it is easy to recognize, by the details of the majority of the successful cases recently recorded in the essays in which the virtues of ipecacuanha are most lauded, that they were sporadic, for the most part mild acute forms; and against the small number of chronic cases reported to have been successfully treated must be offset the contrary results, of the larger clinical experience, of the Eckington and Dreadnought hospitals.‖ We shall not, therefore, be surprised to find that the medical statistics of the British army in India since 1860 give, for certain years, results which by no means correspond with the agreeable picture drawn by Maclean from the statistics of Cornish and Ewart.¶ Indeed, I do not hesitate to express the opinion that really adequate statistics to

---

* *English hospital at Metz, December*, 1870, *January and February*, 1871, The Med. Times and Gaz., Vol. II for 1871, p. 358. The same statemen is made by HEUBNER—*loc. cit.*, next note. BRUNNER—*loc. cit.*, next note—mentions that its use was suggested by him to several of his colleagues in the besieging army who had employed it successfully.

† HEUBNER—S. 545, *op. cit.*, p. 529, *supra*. BRUNNER—*Zur Therapie der Ruhr*, Berliner Klinische Wochenschrift, Jahrg. XIII, 1876, S. 550—declares that he is inclined to regard ipecacuanha in large doses as "die wahre Panacee gegen die einfache nicht komplicirte Dysenterie."

‡ SAVIGNAC—pp. 345-346, *op. cit.*, p. 620, *supra*. The new formula is as follows: "Take 4 grammes of ipecacuanha in powder, boil five minutes in 300 grammes of water, filter and add 30 grammes of syrup of opium and 30 grammes of canella water," (hydrolat de cannelle, *i. e.*, the distilled water; the quantity of French syrup of opium named would contain a little less than 5 centigrammes of opium.) Dose a tablespoonful every hour, or at longer intervals if there is nausea or vomiting. He remarks: "I intentionally employ an abundance of the aqueous vehicle, for the more the ipecacuanha is diluted, the less it irritates the stomach, the less it produces vomiting, the better in fine it is tolerated in every way." SAVIGNAC is reported to have said at the meeting of the Société de Thérapeutique, March 25, 1874, that, in his opinion, "l'ipéca est le médicament par excellence de la dysenterie, de même que le quinine est le médicament des fièvres intermittentes," Bull. Gén. de Thérapeutique, T. LXXXVI, 1874, p. 331. The Brazilian method has recently been successfully used in the epidemic described by CZERNICKI—p. 138, *op. cit.*, p. 651, *supra*—who also gave a combination of ipecacuanha and calomel to the cases that did not yield to ipecacuanha alone, and in either event, after the stools were modified in character, used opium and bismuth.

§ See p. 693, *supra*. ‖ See notes §, and *, last page.

¶ MACLEAN—*loc. cit.*, p. 696, *supra*—says: "Under the old system in Bengal the mortality among Europeans during the forty-two years, from 1812 to 1853-54, amounted to 88.2 in the thousand. During 1860, when large doses of ipecacuanha were given to the almost complete exclusion of all other methods of cure, the mortality was 28.87 in the thousand." These figures are copied from EWART—*loc. cit.*, note †, p. 696, *supra*—in whose paper it will be seen that the ratio for 1860 does not refer to the whole number of cases and deaths of dysentery in Bengal that year, but only to those cases in which ipecacuanha was used; both sets of figures include chronic as well as acute cases. Now by referring to the official *Statistical, Sanitary, and Medical Reports for the year* 1860, Appendix, p. 185, it will be seen that the mean strength of her Majesty's European troops in Bengal that year was 42,371, among whom there were 2,589 cases with 159 deaths of acute, and 561 cases with 43 deaths of chronic, dysentery. This gives a total of 3,150 cases and 202 deaths, or 64 deaths per thousand cases. Of course it will be said that this greater mortality occurred because the majority of the cases were not treated with ipecacuanha. Admit it. What then shall be said of the year 1869, long after the general introduction of this vaunted specific? The official *Report for* 1870, Appendix, p. 613, shows that the mean strength of her Majesty's European troops in Bengal during 1869 was 35,173. The number of cases of dysentery was 1,648, the deaths 105, or 63.7 deaths per 1,000 cases; and it cannot be justly said that the disease in 1869 was more virulent than in 1860, for it will be observed that the ratio of cases to strength was considerably less in the former year than in the latter. Moreover, an examination of the statistics of the European troops in Bengal for individual years from 1812 to 1854—*Statistical report of the sickness and mortality among the fighting men of her Majesty's and the Hon'ble Company's European troops of the Bengal Presidency for* 42 *years*, &c., The Indian Annals of Med. Sci., Vol. IV, 1857, facing p. 266—shows that, although the average mortality from dysentery during that time was as stated above, there were nevertheless individual years, during the reign of calomel and the lancet, when the mortality was even smaller than that for 1860 or 1869: *e. g.*, in 1835, out of an aggregate strength of 11,364 men, there were 1,683 cases and 98 deaths from dysentery, being at the rate of 58 deaths per 1,000 cases; and in the year 1837, out of an

show the comparative value of the ipecacuanha treatment have yet to be collected, for in view of the varying mortality of the disease in different years, and especially in different epidemics, those hitherto brought forward cannot be seriously regarded as conclusive.

Considerable diversity of opinion exists with regard to the mode in which ipecacuanha acts, and better knowledge than we yet possess is desirable to guide its intelligent use in the treatment of the fluxes. While the older physicians for the most part gave it with a view to its emetic, purgative or diaphoretic action, modern attention has been turned away from these obvious and readily obtained effects to its more subtle properties, and especially it has become the fashion to give it in such a way as to avoid emesis as much as possible. Magendie (1817) found that when poisonous doses of emetia, the active principle of ipecacuanha, were administered to dogs a significant enteritis, extending from the cardiac orifice to the anus, was found after death, and the same results occurred when emetia was injected into the jugular vein, the pleural sac, the muscular tissue or given by enemata.* Similar anatomical lesions have more recently been observed by Duckworth, D'Ornellas and Polichronie,† in dogs poisoned by hypodermic injections of emetia, and by the first two of these observers in other animals also.

Pécholier, after poisoning rabbits with emetia given by the mouth, found the inflammation limited to the small intestine, and emphasized this circumstance in connection with the therapeutic use of ipecacuanha in dysentery; but the results on other animals indicate that this is merely an individual peculiarity of the rabbit.‡ Polichronie found that, while large doses of emetia proved speedily fatal by their action on the nervous system, smaller doses, which are supported for a longer time, produced still more profound lesions of the intestinal mucous membrane. Chouppe examined the intestinal mucous membrane of living dogs under the influence of emetia and, finding it dry and anæmic, suggested that this condition may be the primary effect of the first excretion of the poison by the intestinal mucous membrane, and the subsequent congestion and inflammation the consequence of its more abundant elimination.§ In fact the local irritant action of ipecacuanha and its alkaloid

---

aggregate strength of 11,908 men there were 1,478 cases and 91 deaths of dysentery, being at the rate of 62 deaths per 1,000. The experience of such individual years shows that other causes than the change of treatment must be invoked to explain the undoubted fact that the average frequency and fatality of dysentery is less since 1860 than before that date; and we shall not probably err if we conclude that those improvements in hygiene, which have led to the diminution in the frequency of the disease, have also determined its diminished severity and hence a diminished mortality. As a further indication of the sophistry of this attempt to support a doubtful opinion by incomplete figures, I may add that in the United States army during 18 years of peace terminating Dec. 31, 1859—see p. 323 of COOLIDGE'S second report, cited p. 416, *supra*—out of an aggregate strength of 187,144 men there were 22,721 cases and 536 deaths of acute and chronic dysentery, or 23.6 deaths per 1,000 cases, a more favorable ratio than EWART'S reports for cases treated with ipecacuanha, although that method had not yet been employed by any of our military surgeons.

* MAGENDIE et PELLETIER—*Rech. chimiques et physiologiques sur l'ipécacuanha*, Jour. de Pharmacie, T. III, 1817, p. 161. I note that H. C. WOOD—p. 409, *op. cit.*, p. 675, *supra*—remarks: "That the active principle is absorbed, and that the vomiting is so produced, is shown by the experiments of ORFILA"—*Traité de Toxicologie*, 5me Éd., T. I, 1852, p. 651—who, however, merely cites the experiments of MAGENDIE without adducing any of his own.

† DYCE DUCKWORTH—*Obs. upon the action of ipecacuanha and its alkaloid emetia*, St Bartholomew's Hospital Reports, Vol. V, 1869, p. 223; and the same, *Part II*, same reports, Vol. VII, 1871, p. 91. A. E. D'ORNELLAS—*Mémoire sur l'action phys. et thér. de l'émétine*, Gaz. Méd. de Paris, 1873, p. 550. C. A. POLICHRONIE—*Étude exp. sur l'action thér. et phys. de l'ipécacuanha et de son alcaloïde*, Paris Thesis, No. 411, 1874, p. 70 *et seq.*—obtained similar results after both rapid and slow poisoning.

‡ G. PÉCHOLIER—*Rech. exp. sur l'action phys. de ipécacuanha*, Paris, 1862, p. 38—also produced similar physiological effects in a rabbit with emetia absorbed by the skin—p. 23—but appears to have made no dissection in this case. So, too, D'ORNELLAS—*loc. cit.*, last note—found in rabbits poisoned hypodermically, that the vascular injection was limited to the stomach and small intestine. This circumstance is explained by an observation of DUCKWORTH—*loc. cit.* MAGENDIE and subsequent observers had noticed pneumonia as well as enteritis in dogs poisoned by emetia; DUCKWORTH found that "emetia produces most marked effects upon the lungs in the rabbit, and less upon the alimentary canal, while the reverse holds good for the dog, cat, and Guinea pig." I may add that D'ORNELLAS—*loc. cit.*—found that in dogs the intestinal lesions extended further and further towards the lower extremity of the bowel the longer the time that elapsed between the administration of the fatal dose and death.

§ POLICHRONIE—p. 72, *op. cit.*—"intoxication chronique." CHOUPPE—*Étude exp. sur l'action de l'ipéca*, Le Progrès Médical, T. II, 1874, p. 424—concludes: "L'ipéca absorbé par quelque voie que ce soit, semble, au moment même de son absorption, produire une anémie avec sécheresse de la muqueuse intestinale. Peut-être, si l'action du médicament se prolonge, éliminé en plus grande abondance par la muqueuse gastro-intestinale (ce qui resterait à prouver d'une manière irréfutable) que par les autres émonctoires, amène-t-il une congestion consécutive de cette muqueuse, congestion qui peut être portée au point de produire l'inflammation et des hémorrhagies." POLICHRONIE—p. 61 *et seq.*, *op. cit.*—obtained similar results, and adopts the same explanation. At the moment the substance begins to be eliminated it produces a local irritation that gives rise to a vascular contraction—p. 65—which in its turn is followed by congestion and inflammation—p. 70.

is well established by observation,* so that, if it were proven by experiment that emetia introduced into the circulation is actually eliminated by the alimentary mucous membrane,† the occurrence of these local inflammations after its hypodermic injection would be quite intelligible; and it would be readily understood, also, why they should occur more promptly and with greater intensity when the drug, or its alkaloid, is administered by the mouth.‡

Besides these functional and organic lesions of the alimentary canal, the administration of poisonous doses of emetia to animals is promptly followed by grave nervous phenomena. The animal speedily falls into a condition of profound prostration; voluntary motion rapidly diminishes and is soon abolished; reflex action becomes progressively feebler, and death occurs, often preceded by convulsions and paralysis.§ In doses not large enough to prove fatal the prostration is of brief duration and proportioned in degree to the dose,‖ but the effect when observable is always one of depression, and never justifies the assumption of a stimulant action. Experimenters are in accord as to these facts, but differ considerably as to their interpretation. How far the depression results from the gastro-intestinal disturbances;¶ how far it is the consequence of a direct action of the poison in the blood upon some part of the nervous system, and on this latter supposition whether the sensitive or the motor nerve fibres,** the pneumogastric nerves,†† or some portion of the central nervous system‡‡ are immediately affected,—these are interesting questions which have been by no means settled by the experiments hitherto reported.

The phenomena of nervous depression are accompanied by diminished temperature, at least of the surface of the body; but the temperature indicated by a thermometer introduced into the rectum is increased, which D'Ornellas ascribes to the irritated or inflamed condition of the intestinal mucous membrane.§§ The number of respirations is usually, but not always, diminished by poisonous doses of emetia, and it is generally by putting an end to this function that the drug proves fatal, if the animal does not live long enough to

---

* Especially may I cite the paper of DUCKWORTH—*Part II*, p. 102 *et seq.*, *op. cit.*—who produced inflammation of the conjunctiva and prepuce by the local effects of emetia, of the former also by ipecacuanha, and a pustular eruption of the skin by a liniment composed of ipecacuanha, lard and olive oil. PECHOLIER—p. 41, *op. cit.*—produced conjunctivitis in rabbits, and D'ORNELLAS—p. 550, *op. cit.*—in dogs, by introducing powdered ipecacuanha into the eye. The latter observer obtained a similar effect by a solution of emetia.

† The experiments in this direction are by no means conclusive. D'ORNELLAS—p. 551, *op. cit.*—prepared an alcoholic extract of the stomach, intestines and their contents, from a dog poisoned by emetia given hypodermically, and found that when this was injected under the skin of pigeons vomiting and death followed. Unfortunately, POLICHRONIE—p. 93, *op. cit.*—obtained the same results with an alcoholic extract of the stomach of a dog not so poisoned.

‡ This seems probable from the observations of D'ORNELLAS—p. 573, *op. cit.*—who found that it required a larger dose and longer time to produce vomiting when the alkaloid is administered hypodermically than if it be introduced into the stomach.

§ MAGENDIE—*loc. cit.*—described the condition of the poisoned animal as one of sopor, "assoupissement," but this is hardly accurate. The phenomena are described in detail by PÉCHOLIER—p. 42, *op. cit.*—DUCKWORTH—*Part I*, p. 222, *op. cit.*—and D'ORNELLAS—pp. 538, 549 and 552, *op. cit.*

‖ Speedy recovery from great prostration was observed especially by PÉCHOLIER—*loc. cit.*—in rabbits.

¶ Thus DUCKWORTH—*loc. cit.*—remarks: "A decidedly sedative effect is rapidly induced. Magendie observed a disposition to sleep, but I doubt if there is truly a soporific action in poisonous doses; more probably there is a condition akin to, if not identical with, collapse, and this is rendered not unlikely because of the profound impression made on the abdominal nerve centres through the severe gastro-enteric irritation." I may mention here that both PÉCHOLIER—*loc. cit.*—and D'ORNELLAS—*loc. cit.*—record that the administration of a hypodermic dose of emetia is immediately followed by what might be taken, on superficial examination, for a period of excitation; the animal on being let go runs around wildly. This condition, however, is succeeded in a minute or two by the proper effect of the drug, which is always sedative. The latter observer, with apparent reason, attributes this momentary excitement merely to fright.

** PÉCHOLIER—p. 47, *op. cit.*—concluded from experiments on frogs that the paralysis chiefly affected the sensitive nerves, while those of the motor nerves and the contractility of the muscles, though diminished, are not abolished. On the other hand, D'ORNELLAS—p. 539, *op. cit.*—also from experiments on frogs, concluded that the activity of the sensitive nerves is not at all diminished.

†† There seems to be no doubt that section of the pneumogastric nerves before the administration of emetia in most cases prevents vomiting from occurring—DUCKWORTH—p. 223, *op. cit.*—D'ORNELLAS—p. 552, *op. cit.*—POLICHRONIE—p. 86, *op. cit.*; but it does not seem to prevent the gastro-intestinal inflammation or other actions of the poison—D'ORNELLAS—*loc. cit.* See the discussion of the supposed action of emetia on the pneumogastric nerve in these passages.

‡‡ POLICHRONIE—p. 91, *op. cit.*—injected five centigrammes of a 10 per cent. neutral solution of emetia into the carotid artery of a dog without producing vomiting or any other disturbance. Next day he repeated the dose with the same result. He concluded, hence, that emetia has no direct action on the central nervous system by which emesis can be produced. I should be sorry to conclude anything from this single experiment, except that, perhaps, the dose was too small for that particular dog. Nor is much importance to be attached to the fact that both PÉCHOLIER—p. 42, *op. cit.*—and DUCKWORTH—p. 222, *op. cit.*—failed to find anatomical lesions of the central nervous system in animals dead of emetia poisoning.

§§ The fall of surface temperature and rise of rectal temperature are recorded by PÉCHOLIER—p. 35, *op. cit.*—DUCKWORTH—*Part I*, p. 223, *op. cit.*—and D'ORNELLAS—pp. 550–1, *op. cit.* The latter observed, however, that the temperature of the rectum fell first and afterwards rose.

die of the gastro-intestinal lesions.* Still more uncertain is the effect upon the circulation; the pulse is even less frequently retarded than the respiration; no definite modification of the blood pressure has been demonstrated, and the speculation that vaso-motor spasm is produced has not been supported by experiment.† Albuminuria is an occasional accident.‡ Finally, the experiments of Rutherford and Vignal seem to show pretty conclusively that the quantity of the hepatic secretion in dogs is increased by the internal administration of ipecacuanha, certainly a most significant circumstance.§

A consideration of these observations on animals should at least serve as a warning of the danger of recklessly persisting in the administration of large doses of ipecacuanha to patients whose intestinal mucous membrane is already inflamed. That even more moderate doses too long continued may provoke serious intestinal lesions seems likely from the observations of Polichronie on chronic emetia intoxication in dogs;|| so that Blacklock was probably right in speaking of an "ipecacuanha dysentery"¶ as the result of the abuse of this drug in the treatment of the fluxes. Evil consequences of this kind are particularly to be feared from the non-emetic use of ipecacuanha, in which the natural irritability, that would otherwise have expelled the poison from the system, is blunted by the use of morphia. The effects of the medicine upon the bowels, when repeated doses are given in this manner, should always be jealously watched.

Nevertheless the experiments on animals would seem to indicate several ways in which ipecacuanha may prove beneficial to patients laboring under the fluxes, if administered with sufficient caution. The serious perturbation it excites in the intestinal mucous membrane may, when not more than one or two large doses are given at the beginning of the disease, be followed by a beneficial reaction. The experiments show that the effects of such doses are quite transitory, and no serious injury is therefore to be expected from them unless the quantity is large enough to prove immediately poisonous.** It is possible also that repeated doses, provided they are too small to add to the existing inflammation,

* Diminished frequency in the respirations was observed by PÉCHOLIER in rabbits—p. 32, *op. cit.*—by D'ORNELLAS in frogs—p. 538, *op. cit.*—rabbits—p. 550—and dogs—p. 551. DUCKWORTH, on the other hand—*Part I*, p. 220, *op. cit.*—found the respiratory movements increased in frequency. In several of his experiments the animals are said to have died of cardiac paralysis; but D'ORNELLAS found—p. 538, *op. cit.*—that in frogs the heart continued to beat for some time after the respiration had ceased. POLICHRONIE—p. 96, *op. cit.*—remarks that emetia kills in two ways: "Sometimes by the considerable prostration it produces in the nervous system, sometimes when it is given in smaller doses by the intense enteritis it provokes." According to MAGENDIE, DUCKWORTH and D'ORNELLAS, the lungs are generally found congested or actually inflamed, while in the rabbits poisoned by PÉCHOLIER they were always quite anæmic. See note ‡, p. 699, *supra*.

† According to PÉCHOLIER—p. 28, *op. cit.*—the usual effect of the poison is to diminish the frequency and energy of the cardiac pulsations, but D'ORNELLAS—p. 575, *op. cit.*—found this effect less constant than the diminished frequency of the respiration, and DUCKWORTH—*loc. cit.*—found in his experiments that "the cardiac action was not less rapid than in health." Both this author—*Part II*, p. 96—and D'ORNELLAS—*loc. cit.*—failed to establish any modification in the blood pressure. The question of vaso-motor spasm has been investigated especially by POLICHRONIE—p. 61 *et seq.*, *op. cit.*—who concludes "son action vaso-motrice est nulle,"—p. 70.

‡ DUCKWORTH—*Part I*, p. 224, *op. cit.*—states that albuminuria is of frequent occurrence in emetia poisoning, but PÉCHOLIER—p. 40, *op. cit.*—vainly examined the urine of his rabbits for either sugar or albumen.

§ RUTHERFORD and VIGNAL—*Experiments on the biliary secretion of the dog. Second series*, The Jour. of Anat. and Phys., Vol. XI, 1876, p. 74 *et seq.* The quantity of the biliary secretion was increased in these experiments, but analysis showed that "the percentage amount of the special biliary constituents remains unchanged." In two of these experiments 60 grains of ipecacuanha powder were introduced into the duodenum; in two of them only 3 grains, (but these were smaller dogs.) "No purgative effect was produced, but there was an increased secretion of mucus in the small intestine." D'ORNELLAS—p. 551, *op. cit.*—affirmed that the liver, as well as the intestines, eliminates emetia; but conclusive evidence on this head is wanting.

|| POLICHRONIE—see note §, p. 699, *supra*. This author has himself drawn this lesson from his experiments. He remarks, p. 83: "Doses which in themselves are not mortal become so if they are repeated daily for a sufficient time. It will be understood that the number of days will vary with the dose and with the resisting power of the animal. This is an important point to establish in therapeutics, for it shows us that, small as may be the quantity of emetia absorbed from ipecacuanha enemata, it is always necessary to watch the patient and suspend the medicine on the appearance of the first symptoms of enteritis."

¶ BLACKLOCK—see note ‡, p. 696, *supra*.

** An instructive illustration of this possibility has recently been reported—*A case of ipecacuanha poisoning*, The Calcutta Journal of Medicine, Vol. VII, 1874, p. 447. A native student of medicine, aged 23, took about 35 grains of powdered ipecacuanha as an emetic to relieve acidity of the stomach. It was followed by excessive nausea, vomiting and purging, with griping pains in the abdomen, cramps in the fingers of both hands, in the right toe and the calves of the legs. Stiffness in the neck ensued, followed by irregular spasmodic contractions of both upper and lower extremities. There was great prostration and coldness of the extremities; the pulse became soft, weak and slow; the stools were greenish or greenish-yellow, fetid, and contained a good deal of floating white mucus; for a time they were passed involuntarily. The patient recovered. The treatment consisted in the administration of chlorodyne, and of a stimulant mixture containing chloric ether and aromatic spirits of ammonia.

may exercise a wholesome alterative effect upon the intestinal mucous membrane. The action of the drug in increasing the hepatic secretion would also appear to be of great importance in connection with the treatment of the fluxes. This effect has been for some time suspected from the frequency with which the administration of ipecacuanha in dysentery is followed by a prompt improvement in the character of the stools, a circumstance also explained by supposing the drug to relax an imaginary spasm of the biliary ducts.*

Moreover, the sedative action of ipecacuanha, as manifested by its power of sometimes reducing the temperature and diminishing the frequency of the pulse,† indicates for it a certain degree of possible usefulness in those cases of acute dysentery in which the temperature is high and the pulse frequent at the commencement of the disease. But in administering it in these or other cases its tendency to depress the vital powers should never be overlooked. Erroneous views on this subject have prevailed in certain quarters. Already Piso‡ imagined ipecacuanha to exercise a tonic influence upon the viscera. Higginbottom in 1814 ascribed to it general tonic, stimulant and restorative properties, and reaffirmed these views as late as 1869.§ A similar opinion was for a long time held by some of the physicians of the school of Montpellier,‖ and notwithstanding the general discredit into which it has fallen, it has recently been earnestly advocated by my colleague, Surgeon A. A. Woodhull, U. S. Army.¶ Such speculations are at variance with the obvious teachings of clinical experience, which, in this matter, is fully in accord with the experiments on animals and on the healthy human subject.

---

* Among those who have affirmed that ipecacuanha possesses a cholagogue action, I may particularly mention EWART—see note †, p. 696, *supra*. RUTHERFORD and VIGNAL—p. 74, *op. cit.*, last page—remark: "It is stated that it gives rise to evacuations containing a large quantity of bile. The manner in which it does this is not definitely known: some maintaining that it permits of biliary discharge by relieving spasm of the bile-ducts." It is worthy of note that in the experiments of these authors the effect of ipecacuanha in increasing the secretion of bile is somewhat greater than that of sodium sulphate, sodium phosphate or other neutral salts found by them to possess a cholagogue action; see Table II, p. 661, *op. cit.*

† D'ORNELLAS—p. 575, *op. cit.*—gave to a healthy man a subcutaneous injection of emetia in dose insufficient to provoke vomiting, and observed diminished frequency of the pulse and respiration, with lowered temperature both in the rectum and on the surface. Emetia was administered to patients laboring under various diseases; in whatever way it was introduced, and whether it produced vomiting or not, he found that the reduction of temperature in the axilla and retardation of the respiration and pulse were not constant. The respiration was retarded in the majority, the pulse in about half the cases; both effects being especially noted in patients suffering with inflammatory affections of the respiratory organs. The rectal temperature was always accelerated. He concluded that "emetia is neither a vascular tonic, nor a depressor of the circulation, but an irritant of the intestinal tube and a despoiler (un spoliateur) of the blood; it acts by revulsion and spoliation," (evacuation?)

‡ PISO—see note *, p. 692, *supra*—supposed ipecacuanha to exercise a tonic influence on the intestines in consequence of its alleged astringent action, "sed et astringendo viscerum tonum restituat." The astringent action of ipecacuanha does not, however, appear to be very marked. Whatever there is seems to be due to the presence of a small quantity of ipecacuanhic acid, a body belonging to the tannic acid group; see E. WILLIGK—*Ueber die Wurzel der Cephaëlis Ipecacuanha*, Chemisch-Pharm. Central-Blatt, 1851, S. 55.

§ CADE—p. 251, *op. cit.*, *infra*—writes: "Cette propriété de l'ipécacuanha avait été reconnue par un médecin anglais, M. Higginbottom, in 1814. L'ipécacuanha, dit le médecin anglais, possède une propriété tonifiante ou excitante, entièrement opposée à l'action dépressive ou antiphlogistique du tartre stibié." I have not seen any publication of J. HIGGINBOTTOM of the date mentioned, but in 1845 he published a paper on *Ipecacuanha in emetic doses as a powerful restorative in some cases of exhaustion and sinking*, The Lancet, 1845, Vol. I, p. 732, in which he relates that in 1814 he was "first led to see the extraordinary beneficial effects of ipecacuanha as an emetic, in a female forty years of age, who was in a sinking state, in the last stage of cholera," (cholera morbus?) He gave her a scruple of ipecacuanha, and she recovered. He now relates cases of uterine hæmorrhage, bronchitis, suspended animation and sinking during the puerperal state, all cured by ipecacuanha in emetic doses. His views as to its mode of action are sufficiently indicated by the title of the paper. In a later publication—*Ipecacuanha in emetic doses: as a stimulant, restorative, climinative, and adjurant in various cases of disorder and disease*, The British Med. Jour., 1869, Vol. I. p. 143 *et seq.*—he remarks: "The action of an ipecacuanha emetic excites the whole nervous, vascular, and respiratory systems, consequently the heart, the lungs, and the skin; and increases the action of the stomach, intestines, and liver; it acts also as a tonic stimulant to the general capillary organisation, so as to restore and produce a more normal state of the secreting and assimilating organs." He declares that it does not produce "any debility," but that on the contrary he has "often seen the effects in raising quickly the sinking powers of the system in extreme cases of syncope, hæmorrhage, etc." Illustrations of its beneficial effects in "English cholera," fever, erysipelas, bronchitis, tic douloureux, periodical drunkenness, delirium tremens, indigestion, intestinal irritation, suspended animation, exhaustion during the puerperal state, old age, (!) syncope senilis, uterine hæmorrhage and ophthalmia, complete this singular essay.

‖ As to the prevalence of this opinion among the Montpellier physicians, we have the testimony of PÉCHOLIER—p. 8, *op. cit.* A pupil of the Montpellier school, CADE—*De l'ipécacuanha dans la fluxion de poitrine muqueuse*, Bull. Gén. de Thér., T. L, 1856, p. 251—has strikingly formulated these views, contrasting the action of ipecacuanha especially with that of tartar emetic: "Tartar emetic is antiphlogistic, while ipecacuanha in infusion is tonic;" and again: "It is by elevating (en relevant) the tone of the economy, and especially of the lung, that ipecacuanha provokes the absorption of that sanies, 'serum acre, subtile, malignum, efferum, eludens exclusionis ansam, et pepasmi occasionem, a quo siderantur pulmones derepente,' which hepatizes the lung."

¶ Surgeon WOODHULL in his first paper—p. 49, *op. cit.*, p. 697, *supra*—expressed his views in these words: "I therefore regard ipecacuanha as a peculiar but direct nervous stimulant, acting chiefly and probably entirely through the medium of the sympathetic system." The same opinion is expressed in his later work—p. 91, *op. cit.*, same note—where his argument appears to be, that, as ipecacuanha is beneficial "in dysentery, in some of the choleraic forms of intestinal disease, in nervous vomitings, in passive hemorrhages and in intermittent fever," and as "No one will seriously maintain that the indications in these diseases are for depression, and no violence is done to any known physiological or pathological fact in supposing that each of these morbid states may acknowledge a loss of nervous control as its efficient pathological cause. It must follow that the restorative agent is a counter-

The foregoing considerations seem to indicate that the use of ipecacuanha in the fluxes should be limited to vigorous patients suffering with acute catarrhal diarrhœa or dysentery, or with the preliminary catarrhal stage of diphtheritic dysentery. It may perhaps be occasionally useful in the chronic fluxes, but only if there is no ulceration, or if the ulcers are of very moderate extent. It is contraindicated in all exhausted and debilitated patients, and whenever there is conclusive evidence that extensive intestinal lesions already exist. As to the mode of using it, I confess I feel little confidence in small doses frequently repeated, and favor the employment of a single dose of fifteen to thirty grains, according to the vigor of the patient, to be repeated, if deemed necessary, once or at most twice at intervals of twenty-four hours; but I am by no means satisfied, by the evidence hitherto brought forward, that the non-emetic administration of large doses offers any advantages over the old method which secured also its effects as an evacuant. In many of the cases published to illustrate the success of the non-emetic plan it will be noticed that emesis was unintentionally produced without appearing to vitiate the benefits claimed.* Finally, it is worthy of consideration whether emetia may not be substituted for ipecacuanha in the treatment of the fluxes. Some successful attempts in this direction have already been published,† but further studies are desirable.‡

PURGATIVES.—Mild purgation for the purpose of evacuating the peccant humors from the alimentary canal in cases of flux is quite in accordance with the humoral pathology; but the Greek physicians appear for the most part to have relied upon diet and the mildest laxatives for this purpose, and to have avoided the perturbing effects of drastic cathartics. White hellebore, indeed, which had a certain vogue as an emetic, also operated as a purgative, and had its advocates; but the great authority of Galen was thrown against the use of purgatives in the treatment of the alvine fluxes.§ The Arabian writers taught the

depressant, is a stimulant," p. 121, *op. cit.* Such a view as this not only requires that those who hold it should, like my colleague, make light of the results of experiments on animals or observations as to the action of the drug on healthy human beings—see p. 122, *op. cit.*—but is equally at variance with all that we know of the obviously depressing effects of ipecacuanha when administered in sufficient dose to the sick. It will not do to conclude that any medicament is a stimulant merely because patients frequently recover after its administration. I may add that in the interesting monograph just cited, examples are brought forward of apparent benefit from the non-emetic use of ipecacuanha in acute and chronic dysentery, chronic diarrhœa, painful but simple intestinal affections, cholera morbus and cholera infantum, uterine and other hæmorrhages, excessive perspiration, some forms of dyspepsia vomiting of pregnancy, asthma and nervous cough, drunkenness and delirium tremens, opium poisoning, neuralgia, intermittent fever, pneumonia, the puerperal state, acute hepatitis, as an antidote to venom, and as a local application (of the infusion) in conjunctivitis. The disposition to laud the effects of ipecacuanha in a multitude of affections is, however, by no means new, as may be inferred from a remark of PÉCHOLIER—p. 7, *op. cit.*—who, after speaking of its alleged specific virtues in dysentery and puerperal fever, adds: "L'empirisme ne s'arrêta pas là, et la liste de toutes les maladies auxquelles on a prétendu donner l'ipécacuanha pour spécifique, tiendrait ici pas mal de place, si elle n'était trop inutile pour nous arrêter un moment. Citons seulement, dans cette liste, la peste, le tænia, et, d'après Thomson et Cullen, la fièvre intermittente."

* Thus WOODHULL reports—p. 23, *op. cit.*—that even in his own hands vomiting occurred after 10 out of 54 doses given to twenty-six cases "of dysentery or strongly marked dysenteric diarrhœa."

† Thus, according to DUCKWORTH—*Part II*, p. 112, *op. cit.*—Mr. WM. S. ECCLES treated successfully 26 cases of dysentery and 9 of aggravated diarrhœa with emetia. (This was in the Bombay Presidency previous to July, 1869.) "It was always given according to the following formula: Emetiæ gr. iij. morphiæ hydrochloratis gr. ij. sacchari albi gr. xiij. m. ut fiat pulvis. Div. in chartulas vi." See also the remarks of D'ORNELLAS on the administration of emetia in disease—*loc. cit.*, note †, p. 702, *supra*.

‡ I must refer the reader to the works on materia medica, especially that of FLÜCKIGER and HANBURY—*Pharmacographia*, London, 1874, p. 331—for a description of the several varieties of ipecacuanha. Only the root of the cephaëlis ipecacuanha is recognized in the United States Pharmacopœia of 1870. It is worthy of note that, according to so trustworthy an authority as Dr. E. R. SQUIBB, of Brooklyn, much of the powdered ipecacuanha sold in the United States is adulterated. Surgeon WOODHULL—p. 124, *op. cit.*—quotes him as writing, November 11, 1874: "There is very much ipecac. now in the market that is of very doubtful character. It is a large size root, produced in the West Indies, is cheap, and is used either as a substitute or adulterant of the true Rio ipecac. Perhaps half the powdered ipecac. sold may be made from this variety." As this page passes through the press I note the recently reported experience of AUSTIN FLINT—*Diseases of the Alimentary Canal*, (a lecture,) The Medical Record, Vol. XIV, 1878, p. 202—that "in the larger proportion of cases the ipecac. treatment fails."

§ In the Hippocratic treatise *De Affectionibus*—*loc. cit.*, note *, p. 689, *supra*—it is advised that after the administration of hellebore as a phlegmagogue-emetic, and the use of enemata of boiled milk, the bowels should be continually disembarrassed of their contents, provided there is no fever, by the use of unctuous, fat, sweet and moist substances. On the use of fresh vegetables and fruits in dysentery, for their laxative virtues, by the Greek physicians, especially by ALEXANDER OF TRALLES, see p. 678, *supra*. According to CÆLIUS AURELIANUS—*Morb. Chron.*, Lib. IV, Cap. 6, p. 526, edition cited p. 684, *supra*—PRAXAGORAS resorted to purgatives in dysentery, using for this purpose sea-spurge (peplium) with milk and hydromel, (mulsum,) also copious draughts of salt water and the juice of the beet and oil with hydromel, (mulsum.) ARCHIGENES states—in ÆTIUS, Tetrab. III, Serm. 1, Cap. 37, p. 590, edition cited p. 656, *supra*—that certain physicians use purgation by hellebore (veratrum album) in the treatment of the cœliac flux, and that if the strength of the patient be such that the remedy is well borne, it is advantageous above all other remedies. ALEXANDER OF TRALLES—Lib. VIII, Cap. 9, p. 457, edition cited p. 624, *supra*—commends the use of purgation in ulcerative dysentery, when the ulcers are seated in the middle intestines; but it should be employed cautiously, a little at a time. As especially suitable, he mentioned the antidote Theodoretus, (a mixture of

greatest moderation in this matter. According to Avicenna, purgation is sometimes advisable in the treatment of dysentery, but it should be employed with fear and caution, and the mildest substances should be selected; he particularly specified *myrobalans* as suitable for this purpose.* This drug, with two others introduced by the Arabians, *tamarinds*† and *rhubarb*,‡ subsequently acquired great renown in the treatment of dysentery, and their high reputation led to a much more liberal use of purgatives than had been practiced by the ancients. Those of the physicians of the sixteenth and seventeenth centuries who disapproved of bloodletting and emetics, commenced the treatment of dysentery by a purge; those who bled or vomited, followed these preliminary measures by purgation, which was subsequently resorted to at intervals during the progress of the disease. It was generally admitted that violent drastic cathartics were objectionable, and likely to add to the intestinal inflammation; mild laxatives, especially such as produce a subsequent astringent effect, were to be preferred.

Of the three drugs just named *rhubarb* was most frequently employed. To give greater prominence to its astringency by diminishing its purgative action, some advised that it should be torrefied, and a sharp controversy arose as to the precise effects of this

---

cassia and aloes with various aromatics, &c.: see PAULUS ÆGINETA—Lib. VII, Cap. 11, Vol. III. p. 520, edition cited p. 624, *supra*—) either given alone or combined with tears of scammony; also well washed aloes, if it is desired to strengthen the liver. Compare the remarks of ACKERMANN—Lib. II, Cap. 2, p. 133, *op. cit.*, p. 620, *supra*—on the use of laxatives by the ancients in the treatment of dysentery. GALEN—*Ad Glauconem de Medendi Methodo*, Lib. I, Cap. 15, [Ed. Kühn, XI, 43,]—declared that if a patient has fever accompanied with an alvine flux, he will be exposed to great danger if he be bled or purged. He preferred to wash out the acrid juices from the intestines by bland enemata prepared from honey and barley. "Mordacibus succis in intestinis contentis cluentia quum prius per inferiores partes immiserimus, inter quæ mulsa est, ptisanæ cremor et excreta hæc fuerint, morsus deinde mitigantia et quæcunque inhærentia et intestinorum tunicas operientia superne incidentes mordaces humores arcent, in sedem dumus," *Comm. VI, in Hippoc. Epidem.*, VI, § 5, [Ed. Kühn, XVII, B, 329.] The objections of GALEN to any active medication in the treatment of dysentery are strikingly expressed in the treatise *Methodus Medendi*, Lib. XII, Cap. 1, [Ed. Kühn, X, 815,] where he relates that a certain physician who adopted too vehement a plan of medication, although he cured many, killed some of his patients. MOSELEY—p. 295, *op. cit.*, p. 648, *supra*—appears to think that this treatment consisted in giving "raw onions and bread, the patient drinking but little, and the next morning glysters of the sharpest pickle;" but GALEN expressly adds that after the clyster, the rash physician employed a certain "powerful medicine," (*φάρμακον ἰσχυρόν,*) the nature of which he does not state.

* AVICENNA—Lib. III, Fen 16, Tract. 2, Cap. 7, p. 823, edition cited p. 632, *supra:* "Et si fuerit necessaria evacuatio propter malitiam humoris, fac eam cum timore, et cautela. Et stude ut sit solutivum non vehementer nocivum vestigio, et ulceri, imo sit sicut myrobal." Myrobalans were unknown to the Greek physicians. Under this designation several varieties of stone fruits of East Indian and Chinese origin were included: See the commentary of ADAMS—Vol. III, p. 440, of the edition of PAULUS ÆGINETA, cited p. 624, *supra*. They were highly esteemed by the Arabists (*e. g.*, GORDONIUS—*loc. cit.*, p. 680, *supra*) and the physicians of the sixteenth and seventeenth centuries, (see most of the authors cited in note *, next page,) but went gradually out of use during the eighteenth century, and have now long been abandoned.

† Tamarinds also were introduced by the Arabians. According to AVICENNA—Lib. II, Tract. 2, Cap. 699, p. 404, Ed. cited—they are of a cold and dry nature, and have a laxative effect which gently purges yellow bile. They are advantageous in vomiting, as a cooling drink in fever, and in hot intemperaments of the liver: See Lib. III, Fen 14, Tract. 1, Cap. 21, p. 756, *op. cit.* Compare the commentary of ADAMS, Vol. III, p. 439, *op. cit.*, last note. Although some physicians, like FORESTUS—*loc. cit.*, p. 680, *supra*—objected to them as of doubtful value in dysentery, they long enjoyed great popularity. They figured conspicuously in the therapeutics of ZIMMERMANN—*vide infra*—and were still much used in the early part of the present century. Of late they have been seldom employed in the treatment of the fluxes.

‡ According to ACKERMANN—Lib. II, Cap. 2, p. 134, *op. cit.*, p. 620, *supra*—rhubarb was already known to ALEXANDER OF TRALLES and PAULUS ÆGINETA, but according to most modern commentators this is probably erroneous. ALEXANDER OF TRALLES—Lib. VIII, Cap. 3, p. 401, *op. cit.*, p 624, *supra*—indeed mentions "rheum barbaricum" as a remedy for dysentery from imbecility of the liver, but only for its alleged astringent effects. In like manner the chapter of PAULUS ÆGINETA—Lib. VII, Cap. III, Vol. III, p. 316, edition cited note *, *supra*—on Ῥῆον, describes an astringent substance, and says nothing of any purgative effect produced by it. Hence there is much probability in the opinion of ADAMS—Vol. III, p. 479, *op. cit.*—that the rheum rhaponticum or culinary rhubarb was alluded to in these passages. On the other hand, however, PAULUS in another passage—Lib. I, Cap. 43, Vol. I, p 54, *op. cit.*—distinctly recognizes the purgative properties of rhubarb. AVICENNA—*loc. cit.*, note *, *supra*—remarks: "Et reubarbaro quidem inest proprietas mirabilis in ulceribus intestinorum," but this passage occurs in connection with remarks on astringent and styptic remedies; and in his account of "reubarbarum"—Lib. II, Tract. 2, Cap. 585, p. 383, *op. cit.*—he makes no mention of any purgative action from its use. Several of the purgative varieties of rhubarb are, however, described by EBN BAITHAR—I cite the German translation of J. v. SONTHEIMER, *Grosse Zusammenstellung über die Kräfte der bekannten einfachen Heil-und Nahrungsmittel von Abu Mohammed Abdallah Ben Ahmed aus Malaga, bekannt unter den Namen Ebn Baithar*, Stuttgart, 1840, Bd. I, S. 478—who remarks: "As to what concerns the purgative action of this root, it was not noticed by a single one of the older physicians, and no one stumbled upon it until finally more modern physicians appeared who, living nearer our time, acquired a knowledge of it. These were especially inhabitants of our own country," S. 484. (EBN BAITHAR is said to have died in the year 1248.) He affirms that rhubarb is useful in chronic diarrhœas arising from obstructions of the abdominal viscera, and in dysentery; in the latter disease, however, it should be associated with other ingredients to restrain its purgative and increase its astringent and healing powers: See further, on the history of the introduction of rhubarb, the commentary of ADAMS—*loc. cit.*—and the *Pharmacographia* of FLÜCKIGER and HANBURY, London, 1874, p. 442. Another purgative introduced by the Arabians was senna: see the exceedingly interesting treatise of CARL MARTIUS—*Versuch einer Monographie der Sennesblätter*, Leipsic, 1857: also the *Pharmacographia*, p. 189. It has, however, been used in dysentery chiefly as an adjuvant to other purgatives, especially the saline cathartics. Here, too, I may mention manna, the concrete juice of the fraxinus ornus and the f. rotundifolia. The name was given by the Greek and Arabian physicians to other substances, and our modern manna appears first to have been collected in Calabria in the fifteenth century: see DANIEL HANBURY—*Historical notes on manna*, Pharmaceutical Jour. and Trans., Vol. XI, 1869-70, p. 326. It has been used in the fluxes chiefly in combination with senna or other cathartics. DUTROULAU—p. 569, *op. cit.*, p. 618, *supra*—however, used it with whey in place of other purging medicine, giving daily, for several days, 30 grammes of manna in 500 grammes of whey.

modifying process, as to how far it should be carried, and whether it was really desirable.* The popularity of this drug continued during the early part of the eighteenth century;† and Degner went so far as to claim for it the possession of specific powers in bilious diarrhœa and dysentery; he declared that it was a divine rather than a human remedy, and affirmed that it excelled all other purgatives as much as ipecacuanha excelled other emetics.‡ This was the culmination of the renown of rhubarb in the treatment of dysentery; a few practitioners continued to rely upon it;§ Pringle, Macbride and Geach combined it with calomel to increase the certainty and ease of its operation;‖ but the general use of the drug had brought into notice various inconveniences. Baker pointed out that its action was often tardy, insufficient, accompanied by an increase of the tormina; and condemned its use altogether, especially at the beginning of the disease;¶ Zimmermann, although he admitted that it was of singular service in the latter stages of dysentery, raised similar objections to its employment at the beginning; and Cullen went so far as to declare that it is one of the most improper purgatives that can be used in this affection.**

After this rhubarb was long neglected,†† but of late years it has been again brought into use in dysentery. It is praised by Barrallier and Heubner,‡‡ but I am inclined to agree with Savignac in adopting the practice of Zimmermann and reserving it for the later stages of the disease,§§ when perhaps the astringent effect which follows its cathartic

* The doctrines sketched in the text were more or less fully expressed by each of the following writers: ALTOMARUS—*loc. cit.*, p. 680, *supra*—and NICOLAUS PISO—*loc. cit.*, p. 684, *supra*—the first preferred rhubarb torrefied, the second untorrefied. HOLLERIUS—*loc. cit.*, p. 680, *supra*—affirmed that no medicine is more excellent for dysenteries than rhubarb. It may be used not only to purge once, but, if the symptoms require and the strength permit, may be repeated frequently. RONDELETIUS—*loc. cit.*, p. 680, *supra*—censured those who used torrefied rhubarb, which he says is rendered acrid by the empyreumatic matters generated by the heat. FORESTUS—*loc. cit.*, p. 680, *supra*—remarked that although certain illustrious physicians have objected to the use of rhubarb and myrobalans, they are not to be rejected because GALEN did not know them; for if he had he would undoubtedly have used them. He held that torrefied rhubarb should not be used at the beginning of dysentery, and that tamarinds are of doubtful value in that disease. FAB. HILDANUS—Cap. 8, p. 681, *op. cit.*, p. 644, *supra*—thought that torrefied rhubarb only should be used. FELIX PLATER—T. III, p. 809, *op. cit.*, p. 680, *supra*—cautioned against overtoasting the rhubarb. SEPTALIUS—*loc. cit.*, p. 680, *supra*—held, contrary to the general opinion, that moderate torrefaction rather increased than diminished the purgative properties of rhubarb. SENNERTUS—T. III. p. 132, *op. cit.*, p. 645, *supra*—advised that rhubarb should not be torrefied, and that purgation should be repeated until all the vicious humors are expelled: "Neque solum semel purgandum, sed aliquoties hoc faciendum, donec humor vitiosus maxima ex parte sublatus sit," p. 134. In Quæstio IV, "An purgantia exhibenda sint in dysenteria?" he criticises those who, like ALEXANDER MASSARIA and VALLESIUS, have too slavishly obeyed the caution of AVICENNA—see note *, last page—and altogether rejected the use of purgatives in dysentery. Compare also ZACUTUS LUSITANUS—*Praxis Hist.*, Lib. Ult., No. VI, T. II, p. 635, *op. cit.*, p. 665, *supra*; RIVERIUS—p. 302, *op. cit.*. p. 680, *supra*; and ROLFINCIUS—p. 298, *op. cit.*, p. 681, *supra*. I may add that SYLVIUS—*Prax. Med.*, Lib. I, Cap. XIII, § 56, p. 184, edition cited p. 690, *supra*—laid great stress on the use of toasted rhubarb combined with a grain of "laudanum opiatum." WILLIS—*loc. cit.*, p. 689, *supra*—declared that in the London dysentery of 1670 any evacuation, whether bloodletting, purging or vomiting, was always hurtful; but in the bloody flux of 1671 he gave a "purging yet strengthening" potion of rhubarb, myrobalans, &c., after having first, however, moderated the flux with mild astringents, "liquid laudanum," &c., p. 79. And SYDENHAM—Vol. I, p. 170, *op. cit.*, p. 407, *supra*—although he held that rhubarb alone was "not worth much in fluxes," always followed bloodletting with his "usual lenitive cathartic," composed of tamarinds, senna leaves, manna, rhubarb, &c.

† See, for example, HOFFMANN—T. III, p. 155, *op. cit.*, p. 681, *supra*; VAN SWIETEN—T. II, § 722, p. 391, *op. cit.*, p. 663, *supra*; and TISSOT—T. III, p. 9, *op. cit.*, p. 625, *supra*.

‡ DEGNER—Cap. 3, § 31 *et seq.*, p. 140 *et seq.*, *op. cit.*, p. 625, *supra*. He gave ROLFINCK's tincture, consisting of half an ounce of rhubarb, a drachm of salt of tartar and five or six ounces of chiccory water or mint water, p. 144. Of this he says: "Præterea divinum potius quam humanum remedium hanc Rhei Tincturam adpellare licebit," Cap. 5, § 15, p. 271.

§ For example. HILLARY—p. 209, *op. cit.*, p. 681, *supra*—after administering an emetic of ipecacuanha, gave "a dose of torrefied rhubarb mixed with an opiate, to procure the distressed patient some respite and ease, and abate the flux."

‖ PRINGLE—p. 262, *op. cit.*, p. 640, *supra*—after the emetic—see p. 693, *supra*—gave next morning five grains of calomel with twenty-five or thirty of rhubarb. He adds: "At first I gave the rhubarb without any calomel, and usually about half a drachm; but afterwards I found it necessary either to give double that quantity for a dose, or to join the calomel to thirty grains, in order to procure a thorough passage." He afterwards "generally endeavoured to finish the cure by combining purges with opiates," p. 268. MACBRIDE—p. 465, *op. cit.*, p. 664, *supra*—followed the same practice, but gave smaller doses: "A scruple or twenty-five grains of rhubarb, with two or three grains of calomel." GEACH—p. 21, *op. cit.*, p. 660, *supra*—followed the emetic by four grains of calomel and thirty of rhubarb.

¶ BAKER—p. 28, *op. cit.*, p. 437, *supra*. He also objected to calomel and rhubarb, p. 29. At a still earlier period BONTIUS—*De Med. Indorum*, Lib. III, Cap. 3, p. 65, *op. cit.*, p. 681, *supra*—reported that the common mode of treating dysentery in the Indies by an infusion of rhubarb in a decoction of tamarinds was an uncertain method, which often caused the destruction of the patient. He thought that restoratives were required rather than purging.

** ZIMMERMANN—Cap. VI, S. 121, *op. cit.*, p. 648, *supra*; yet he sometimes gave rhubarb, combined with his favorite cream of tartar, to peasants, Cap. V, S. 84. For his praise of its use in the latter stages of the disease, see S. 106: "Am Ende der Krankheit diente mir die Rhabarber ungemein." CULLEN—*First Lines*, § 1080, Vol. II, p. 324, *op. cit.*, p. 648, *supra*.

†† Among those who have condemned the use of rhubarb I may mention FOURNIER et VAIDY—pp. 378 and 395, *op. cit.*, p. 362, *supra*; HAUFF—S. 403, *op. cit.*, p. 534, *supra*; and NAUMANN—Bd. IV, Abth. 2, S. 83, *op. cit.*, p. 645, *supra*.

‡‡ BARRALLIER—p. 777, *op. cit.*, p. 603, *supra*—enumerates calomel, rhubarb, manna, whey, tamarinds, cream of tartar and the neutral salts as the best purgatives in dysentery. HEUBNER—S. 545, *op. cit.*, p. 529, *supra*—is equally eclectic. He prefers castor oil, indeed, but thinks the effects of tamarinds, rhubarb, ipecac. in small doses, calomel, or the tartrates and sulphates quite the same; with these to choose from it is easy to prepare a dose to the taste of the patient.

§§ SAVIGNAC—p. 364, *op. cit.*, p. 620, *supra*.

action may prove serviceable. It is true that the recent experiments of Rutherford and Vignal indicate that it possesses the power of stimulating the hepatic secretion,* but the same power is enjoyed to a still higher degree by several saline cathartics which are more certain in their action and less likely to gripe or to irritate the inflamed mucous membrane. In catarrhal diarrhœas and in the chronic fluxes it has probably a greater range of usefulness; but the great variability in the quality of the drug, as actually found in the American market, constitutes a serious objection to its employment.†

During the seventeenth century attention was directed to the medicinal value of two neutral salts which subsequently enjoyed considerable popularity in the treatment of dysentery. The first was the *sulphate of soda*, which Glauber obtained by the action of oil of vitriol on common salt, and named *sal mirabilis*.‡ The second was *sulphate of magnesia*, the *sal catharticus amarus* of Nehemiah Grew, who prepared it by evaporating the water of the famous medicinal springs at Epsom.§ The sal catharticus was employed in dysentery by Cleghorn, and lauded above all other purgatives for this purpose by Baker and Donald Monro.‖ Cullen commended Glauber's salt, while Hunter, Wade and Christie used either indifferently.¶ Both Cleghorn and Pringle attached great importance to the evacu-

---

* RUTHERFORD and VIGNAL—Vol. X, p. 273, *op. cit.*, p. 701, *supra*.

† Consult on this subject E. R. SQUIBB—*Note on rhubarb*, Proc. of the Amer. Pharm. Ass., 16th annual meeting, 1868, p. 452; *Note on rhubarb. For* 1869, same Proc., 17th annual meeting, 1869, p. 398; and *Note on rhubarb*, same Proc., 18th annual meeting, for 1870, p. 180. From these papers it is quite clear that good rhubarb can be had by those who are willing to pay for it, if they know of whom to buy. It is also clear that the market is flooded with inferior grades.

‡ J. RUDOLPH GLAUBER, a celebrated chemist, who lived at Amsterdam, where he was born about the beginning of the seventeenth century, prepared this salt by lixiviating and recrystalizing the fixed salt remaining at the bottom of the retort after the preparation of his newly discovered spirit of sea salt. The supposed virtues of the sal mirabilis, both when administered internally and as an external application to wounds and ulcers, are described at length in his *Tractatus de natura salium*, (1658, in German;) I cite the Latin version, Amsterdam, 1659, p. 61 *et seq.*, where the method of preparation is not distinctly given, and it is alleged that it can also be made out of saltpetre and other salts, showing that other sulphates were confounded by him with the soda salt. See, for his process in detail, H. BOERHAAVE—*Elementa Chemiæ*, (1724;) I cite the English translation, London, 1741, Vol. II, p. 260—who also states that GLAUBER sometimes melted with his salt a small quantity of antimony, a practice which seems to be the germ of the mixture of tartar emetic with this and Epsom salt, used by Sir GILBERT BLANE and others: see note §, p. 691, *supra*.

§ NEHEMIAH GREW—*Tractatus de salis catharctici amari in aquis Ebeshamensibus et hujusmodi aliis contenti natura et usu*, London, 1695; I have not been able to see this work, and cite from MANGETUS—*Bibl. Script. Med.*, Geneva, 1731, T. I, Pars 2, p. 521—who has given an abstract of its contents. How rival establishments were set up, first at the springs on one side of Shooters-Hill in Kent, about the year 1700, and subsequently at other places, and how an imitation Epsom salt was afterwards manufactured from Bittern at the salt works, is related by Mr. JOHN BROWN, chymist—Philosophical Transactions abridged, Vol. VII, London, 1734, p. 729. The sulphate of magnesia is now manufactured on a large scale from dolomite. Perhaps even earlier than by the springs at Epsom, great renown, on account of their efficacy in dysentery, was acquired by the two springs Bagnuolo and Tettuccio at Mount Catini in Tuscany, which, according to CONSTANTIN JAMES—*Guide Pratique aux Eaux Minérales Françaises et Étrangères*, 5me Éd., Paris, 1861, p. 364—contain chiefly chloride of sodium associated with smaller quantities of sulphates, carbonates, &c. These are the springs so extravagantly praised for their efficacy in dysentery by GABRIEL FALLOPPIUS—*De Thermalibus Aquis*, (1564,) Cap. 28, Opera, Venice, 1606, T. I, p. 326; and ANDREAS BACCIUS—*De Thermis*, Venice, 1588, Lib. III, p. 134, and Lib. V, p. 277. Want of space prevents me from discussing various other salines introduced by the iatro-chemical school. They were for the most part condemned by HOFFMANN—T. III, p. 157, *op. cit.*, p. 681, *supra:* "Summo quoque studio fugienda sunt illa remedia quæ intestina magis stimulant; veluti sunt cuncta salia, neutra ac digestiva, tartarus vitriolatus, arcanum duplicatum, salia thermarum, &c. Nihilo minus nitrum, nec non sal prunellæ, quod præsertim Riverius magnis extollit laudibus, ob vim refrigerantem atque temperantem quandoque commendari, et absorbentibus immisceri meretur pulveribus, utique, si æstus cum siti nimium urgeant, et subjecta cholericæ, biliosæque sint constitutionis." DEGNER—Cap. V, § 19, p. 576, *op. cit.*, p. 625, *supra*—made no such exception, remarking: "Sales omnes ex. gr. Tartar. vitriol. Arcan. duplic. Sal polychrest. Sal prunel. &c. contra omnem sane rationem ac prudentiam medicam ab aliis toties præscripti, mordaces sunt, et in intestinis exulceratis nil nisi graviores dolores et stimulos excitant, quare ne Nitrosa quidem, imprimis in statu et progressu morbi, tuta erant; fluxum enim magis exacerbasse observavi."

‖ CLEGHORN—Cap. V, p. 252, *op. cit.*, p. 637, *supra*—advised purgatives of the mildest kind, "such as whey, weak broth, sweet oil, solution of manna, cremor tartari, &c.;" but if these did not succeed, he gave six or seven grains of calomel with a grain of opium at night, and the next day "a purging apozem made of senna, manna, and sal cathartieum." BAKER—*loc. cit.*, last page—recommends that mild catharties, such as infusion of senna, manna and tamarinds be tried first; but if neither natural fæces nor scybala are brought away, more active purgatives should be tried, "ante omnia, ad salem cathartieum amarum (quo nihil fere quidpiam aut certius aut citius alvo moranti calcar addit) protinus transeundum." DONALD MONRO—p. 70, *op. cit.*, p. 625, *supra*—after repeated trials, found that rhubarb did not answer so well in the first stage of dysentery as "the sal cathartieum amarum, with manna and oil." He adds that Mr. FRANCIS RUSSEL, in the year 1756, when dysentery was very fatal at Gibraltar, found nothing to "contribute more to the cure, than repeated doses of these salts."

¶ CULLEN—*loc. cit.*, last page—recommended "a dose of Glauber's salts, 3ss. twice a day, or cremor tartari employed in the same manner." If this did not suffice to bring on evacuations by stool without pain and griping, he resorted to "tartar emetic, given in small doses and at such intervals as may determine their operation to be chiefly by stool." J. HUNTER—p. 229, *op. cit.*, p. 637, *supra*—says that in his experience with purgatives, "the bitter purging salt, or Glauber's salt," was found the best. J. P. WADE—*Select evidences of a successful method of treating fever and dysentery in Bengal*, London, 1791—used in dysentery a solution of an ounce or an ounce and a half of "either Glauber or bitter salts, to twenty ounces of water," sometimes with the addition of cream of tartar, manna, sugar or peppermint; one or two grains of tartar emetic were often added. This solution was given in doses of about two ounces every hour till it operated very freely by stool. He reports 45 cases in detail. J. CHRISTIE—*On the nature and causes of dysentery*, The Med. and Phys. Jour., Vol. I, 1799, p. 465—gave an ounce or an ounce and a half of GLAUBER'S salt, or of sulphate of magnesia, with or without a little manna, as the first dose. If the gripings continued, he gave a second dose of six drachms to an ounce of the same salt. If the disease was not checked, he pursued the treatment, as CULLEN did, by administering small doses of tartar emetic so as to act on the bowels.

ation of scybala, and regarded this as a prominent indication for the administration of cathartics in dysentery.* Cullen taught that the formation of scybala resulted from a preternatural spasmodic constriction of the colon, and insisted upon cathartics as the best means of relaxing this spasm.† These views, which were by no means brought into conflict with the older opinions as to the evacuation of bile and other morbid humors, gave additional prominence to the employment of cathartics in dysentery, and the neutral sulphates enjoyed their full share of popularity. Some used purgative doses of either salt alone, or combined with manna or senna; others employed the combination of salts and tartar emetic, as advised by Sir Gilbert Blane,‡ while Heberden recommended the administration of sulphate of magnesia in drachm doses, repeated every six hours, and claimed that it relieved the pain even before it operated as a purge.§

It is unnecessary to discuss all the other saline purgatives that found occasional employment in dysentery during the seventeenth and eighteenth centuries. It will be sufficient to refer to *cream of tartar*, long before occasionally prescribed, but first brought into prominence by the laudations of Zimmermann;|| and *Rochelle salt*, commended for use in diarrhœa and dysentery by its inventor, Seignette, which, however, failed to obtain much favor for this purpose until more modern times.¶

The great popularity acquired by calomel as a cathartic in dysentery during the early part of the present century, and the discredit into which purgation subsequently fell, caused the use of the saline purgatives to fall into comparative neglect. Nevertheless they have not remained without advocates, especially in France, where the influence of Bretonneau and Trousseau was exerted in their favor.** At the beginning of our civil war the use of purgative doses of Epsom salt combined with a little tartar emetic was advised by Tripler, while Stillé commended small laxative doses of Epsom or Rochelle salt in inflammatory dysentery.†† Both these methods were extensively used for a while by our surgeons in the field; but Tripler's plan was soon pretty generally modified by omitting the tartar

* See note *, p. 353, *supra*. † *Loc. cit.*, p. 705, *supra*. ‡ See note §, p. 691, *supra*.

§ WM. HEBERDEN—*Comm. de morb. hist. et cur.*, (1802,) Ed. altera, London, 1807, p. 134.

|| Cream of tartar is mentioned among the mild laxatives suitable for use in dysentery by CLEGHORN—*loc. cit.*, note ||, last page. ZIMMERMANN—Cap. 5, S. 82, *op. cit.*, p. 648, *supra*—followed his emetic of ipecacuanha—see p. 693, *supra*—by a drink composed of two ounces of barley and an ounce of cream of tartar, boiled in two pints and a half of water till the barley bursts, and then strained through a linen cloth. On the second day, in the morning, he gave three ounces of tamarinds boiled in half a pint of water and strained. During the night following he repeated the barley water with the cream of tartar. On the third or fourth day he repeated the tamarind decoction, continuing the barley water and cream of tartar in the mean time. Sometimes he gave an ounce or an ounce and a half of Sedlitz salt (sulphate of magnesia) instead of the tamarinds. CULLEN—*loc. cit.*, last page—sometimes gave cream of tartar in the same way that he did Glauber's salt. It was employed by SELLE—*Med. Clinica*, 7te aufl., Vienna, 1797, S. 145—and found efficacious even in serious cases by CHEYNE—p. 48, *op. cit.*, p. 686, *supra*.

¶ PETER SEIGNETTE, an apothecary at Rochelle—see J. BECKMANN'S *History of Inventions and Discoveries*, English Transl., 2d Ed., London, 1814, Vol. IV, p. 616—published an account of this salt as an arcanum in the year 1672; this I have not been able to find, but according to G. L. ENCKELMANN—*Diss. de sale alkali de Seignette ejusque natura et usu*, Strasburg, 1756, p. 22—he commended it in the treatment of diarrhœa and dysentery, against which ENCKELMANN protests, unless indeed the diarrhœa takes its origin in mucus, or some other tenacious material obstructing the intestines. SEIGNETTE called his arcanum *sal alkali;* it was also known as the *sal polychrestus Seignette*, or *soluble sal polychrestus*. Its composition was made known in 1731 by BOULDUC—Mém. de l'Acad. des Sci., année 1731: see *Collection Academique*, T. VII, Paris, 1784, p. 281—and GEOFFROY—Phil. Trans., abridged, Vol. IX, 1747, p. 393.

** TROUSSEAU et PARMENTIER—T. XIV, p. 33 *et seq*, *op. cit.*, p. 439, *supra*—report several cases successfully treated by BRETONNEAU in the hospital at Tours during the epidemic of 1826 by repeated doses of Epsom salt. TROUSSEAU himself—T. III, p. 167, *op. cit.*, p. 664, *supra*—continued to employ this plan, and used it with success in various epidemics. He reports that it was also successfully employed during the epidemic which prevailed in 1842 in the garrison at Versailles, and that, in preparing the report on epidemics in France for the Academy of Medicine, he found that almost all the physicians, whose reports he examined, employed as their principal means of combating dysentery "purgatives, above all the neutral salts, such as sulphate of soda, sulphate of magnesia and Rochelle salt, (le sel de Seignette.)" Compare TROUSSEAU—*Rapport sur les épidémies qui ont régné en France en* 1856, Mém. de l'Acad. Imp. de Méd., T. XXII, 1858, p. LXXXVIII; also the *Rapport*, &c., for 1857, same Mém., T. XXIII, 1859, p. XLV. See also BARRALLIER—*Note sur une épidémie de dysenterie, observée a l'hopital de la marine de Toulon pendant l'année* 1859, L'Union Méd., N. S., T. X, 1861, p. 504—who gave the preference to Rochelle salt, of which in mild cases of dysentery he administered 15 grammes twice a day until the blood disappeared from the stools and they regained the diarrhœic characters.

†† C. S. TRIPLER—*loc. cit.*, p. 691, *supra*. STILLÉ—p. 334, *op. cit.*, p. 650, *supra*—says: "Epsom salts, or, still better, Rochelle salts, in the proportion of one ounce of either to a quart of water, of which a wineglassful is given every two hours, will generally in the course of a few hours diminish or even suspend entirely the tenesmus and produce a free discharge of bilious and watery stools. After this treatment has been pursued for eighteen or twenty-four hours, it should be suspended for an equal space of time, and meanwhile doses of three or five grains of Dover's powder repeated at intervals of three hours, after which the saline may be resumed as at first. Two or three such courses are generally sufficient," &c.

emetic, and the Epsom salt was given alone, or combined with other purgatives, especially senna and rhubarb, or used to follow a purgative dose of blue mass or calomel. Each of these plans had its advocates, but those who gave the salt uncombined were probably in the majority.* Rochelle salt was used to but a moderate extent during the war, and sulphate of soda was not supplied by the Purveying Department of the Army.†

This neglect of sulphate of soda, which at that time was popularly regarded in the United States as fit for horses rather than men, is certainly to be regretted. Not merely is the old renown of this salt sustained by the recently published clinical observations of Méry,‡ but the experiments of Rutherford and Vignal furnish reasonable grounds for preferring it to the sulphate of magnesia in the treatment of dysentery. These experiments show pretty conclusively that sulphate of soda produces a decided increase in the hepatic secretion, while sulphate of magnesia does not. The same experimenters found that a similar increase in the hepatic secretion was produced by sulphate of potassa, phosphate of soda and Rochelle salt;§ a circumstance which seems to justify the preference expressed by Savignac, on the grounds of clinical observation, for the phosphate of soda and Rochelle salt as purgatives in dysentery rather than sulphate of magnesia.‖ My own personal experience, so far as it goes, strongly inclines me to favor the sulphate of soda; but I suppose the other salines just named might be substituted with equal advantage, and that the Epsom salt is the least desirable of the saline purgatives for the treatment of dysentery.

Another cathartic that has enjoyed a great reputation in the management of this disease is *castor oil.* Well known to the Greek physicians,¶ who do not, however, appear to have

---

* TRIPLER's method is lauded in Section II by WOODWARD—p. 51, *supra*—and SCHEETZ—p. 80, *supra.* R. R. MCMEENS, surgeon 3d Ohio vols.—*Letter from Meridith hospital, Nashville*, The Cincinnati Lancet and Observer, Vol. V, N. S., 1862, p. 351—reports that it was the favorite remedy with him. Saline purgatives, or small doses of the salines, for the most part Epsom salt, but in some instances Rochelle salt, are spoken of with approval in Section II by STORROW—p. 43, *supra;* SCHÜSSLER—p. 44, *supra;* EZRA READ—pp. 66 and 100, *supra;* VOLLUM and LEE—p. 71, *supra;* MCDONALD—p. 78, *supra;* HOYT—p. 80, *supra;* HARRISON—p. 82, *supra;* POTTER and BIGELOW—p. 83, *supra;* REYNOLDS—p. 84, *supra;* MCCLURE—p. 85, *supra;* GRANGER, PECK and GRIMES—p. 86, *supra;* MILLER—p. 89, *supra;* FOOTE and MCMILLEN—p. 90, *supra;* PYLE and BLADES—p. 91, *supra;* COOK—p. 93, *supra;* HUNT, p. 94, *supra;* and BIDWELL—p. 96, *supra.* Combined with or following a mercurial cathartic they are commended by JEWETT—p. 79, *supra;* MERRITT—p. 80, *supra;* and SANBORN—p. 94, *supra.* See also the testimony in favor of sulphate of magnesia as a laxative or purgative, of WM. HENRY THAYER—*An inquiry into the therapeutic value of sulphate of magnesia, oil of turpentine, and calomel in inflammation of the intestinal mucous membrane, especially in dysentery*, The Berkshire Med. Jour., Vol. I, 1861, p. 342; Surgeon P. C. PEASE, 6th N. Y. vols.—*Health of Wilson's Zouaves*, The Amer. Med. Times, Vol. III, 1861, p. 159; T. H. WALKER—*Camp diarrhœa*, The Chicago Med. Jour., Vol. XIX, 1862, p. 478; A. A. Surg. HENRY M. LYMAN—*Remarks on the prevailing diseases in the hospitals at Nashville, Tennessee*, The Amer. Med. Times, Vol. VI, 1863, p. 16; Asst. Surg. JEHU LITTLE, 24th Mo. vols.—*Camp dysentery*, The Chicago Med. Jour., Vol. XX, 1863, p. 505; and J. R. BLACK—*Camp diarrhœa*, The Cincinnati Lancet and Observer, Vol. VII, 1864, p. 262.

† Although of course these purgatives were used for many other purposes than the treatment of dysentery, yet some notion of their comparative popularity may be gathered from the statement of Surgeon W. C. SPENCER, U. S. A., according to which the quantity of sulphate of magnesia purchased during the civil war was 515,828 pounds; of Rochelle salt, 49,909 pounds. From the same statement I abstract the following quantities of other cathartics purchased during the war: Aloes, in powder, 5,916 lbs.; rhubarb, in lump, 3,476 lbs.; rhubarb, in powder, 8,284 lbs.; fluid extract of rhubarb, 16,125 lbs.; magnesia, calcined, 10,512 lbs.; podophyllin, 523 lbs.; castor oil, 220,354 quarts; calomel, 10,376 lbs.; jalap, in powder, 1,775 lbs.; compound cathartic pills, (of the U. S. Pharmacopœia,) 683,131 dozen.

‡ F. C. MÉRY—*De la dysenterie des pays chauds et de son traitement spécialement par le sulfate de soude*, Paris Thesis, No. 257, 1875. These observations were made on a French naval vessel, the Venus, stationed for eleven months on the western coast of Mexico during the French occupation, subsequently on the Calvados during a voyage around the world, and in the hospital ship Finistère carrying sick from Cayenne, Martinique and Guadeloupe back to France. The author claims to have obtained great success in the acute cases, and even in the chronic cases, in which tonics were the principal part of the treatment; the sulphate of soda always improved the character of the stools and relieved the anal and vesical tenesmus. He gave the first day 15 to 20 grammes of sulphate of soda dissolved in 80 to 150 grammes of water, divided into four doses. Afterwards the daily quantity was gradually diminished to as little as 4 or even 2 grammes daily, given in divided doses. He found it moderated the fever, diminished the number of the stools, and favorably modified their nature: they became at first sero-bilious, then feculent. The anal and vesical tenesmus were promptly relieved, and the tormina usually ceased after the first dose.

§ RUTHERFORD and VIGNAL—Vol. XI, p. 623, *op. cit.*, p. 701, *supra*—obtained the effects stated in the text by purgative doses of the salt injected into the duodenum of dogs. The purgative action of sulphate of magnesia was accompanied by an actual diminution of the secretion of bile.

‖ SAVIGNAC—p. 362, *op. cit.*, p. 630, *supra*—says that sulphate of soda and sulphate of magnesia have been praised by many physicians, but that he prefers to them the phosphate of soda, the tartrate of soda, or the tartrate of soda and potassa. His reason is that the action of these salts is more gentle, although they are equally efficient as purgatives.

¶ DIOSCORIDES—Lib. IV, Cap. 164, fol. 245, *op. cit.*, p. 623, *supra*—described the castor-oil plant under the name of *κίκι* or *κρότων*, and says that its seeds purge phlegm, bile and water from the bowels, and excite vomiting. Its oil is unfit for food, but useful for external applications; he speaks of it as *κίκινον ἔλαιον*. In Lib. I, Cap. 38, fol. 19, *op. cit.*, he describes the then used process of manufacturing it, and enumerates various external disorders in which it is useful, such as psora, ulcers of the head, &c. According to GALEN—*De Simp. Med. Temp. ac Fac.*, Lib. VII, Cap. X, § 24, [Ed. Kühn, XII. 26.]—the oil made from the seeds of this plant is of a warm temperament, and may be substituted for the oil of radish—*De Succedaneis Lib.*, [*id.*, XIX, 741:] "Pro raphanino oleo, ricininum oleum." Elsewhere—*Comm. VI, Sect. VI, in Hippoc. Epidem.* VI, § 5, [*id.*, XVII, B, 327,]—in speaking of the usefulness of certain oils in relieving pain when externally applied, he classes castor oil with the oils of laurel, cedar, mustard and radish.

used it in the treatment of the fluxes; it seems to have been entirely forgotten, when attention was again directed to it in 1764, by the dissertation of Peter Canvane.* The reputation it speedily acquired as a mild but efficient cathartic soon led to its employment in dysentery, especially by the English physicians. John Clark, though he recognized that it was unfit for use when rancid, and plainly indicates by the language of his very laudation that the stomachs of his patients sometimes rebelled against it, praised it as one of the very best purges in this disease.† Johnson regarded it as almost the only purgative that is proper in dysentery, but found it sometimes necessary to increase its activity by adding a few grains of calomel.‡ An equally favorable opinion was entertained by Bampfield, who, recognizing undecomposed oil in the stools, imagined that it did good by smearing the mucous surface and thus protecting it from irritation by the morbid secretions.§ Both Baly and Copland gave castor oil the preference over other purgatives in dysentery.‖

It is true that Cheyne observed that it often aggravated the tormina and tenesmus, but he did not on that account abandon it; he advised instead that it should be combined with laudanum or oil of turpentine. For the same reason the combination with laudanum was employed by Bankier,¶ who objected to the admixture of oil of turpentine as too stimulating and as apt to nauseate. Such objections did not, however, interfere with the general popularity of castor oil among English physicians. Alone, or in some one of the combinations mentioned, it was extensively used. It soon found many admirers on the continent also, where its employment in dysentery has been praised by Bamberger, Vogt, Savignac, Niemeyer and Heubner.** In the United States this use of castor oil, which had been strongly recommended by George B. Wood, and approved in the tract of Stillé, at least for mild dysenteries,†† was brought into pretty extensive service during the civil war.‡‡ Indeed, castor oil was very frequently resorted to by our military surgeons whenever a cathartic was desired for any purpose, as is shown by the circumstance that nearly a quarter of a million quarts were purchased by the Purveying Department of the Army during the

---

* PETER CANVANE—*Diss. on the oleum palmæ christi*, &c., 1764; I have not been able to see a copy of this essay, which is cited in the *Pharmacographia*—p. 511, *op. cit.*, p. 704, *supra*.

† JOHN CLARK—*Obs. on the Diseases which prevail in Long Voyages to Hot Countries*, &c., (1773,) 3d Ed., London, 1809, p. 221: "Castor oil, when properly prepared, and not grown rancid by keeping, I have found to be one of the best purges in the dysentery. It seems to be possessed of an anodyne quality, frequently easing the painful gripes as soon as taken, and seldom fails, when it agrees with the stomach, to procure copious evacuations." Among the earlier writers who mention castor oil as a suitable purgative in dysentery I may mention J. HUNTER—p. 239, *op. cit.*, p. 637, *supra*.

‡ JAMES JOHNSON—p. 234, *op. cit.*, p. 682, *supra*.

§ R. W. BAMPFIELD—p. 124, *op. cit.*, p. 682, *supra:* "The oleum ricini is perhaps better calculated to afford relief in dysentery, than any other aperient or cathartic; for its action is not only mild and generally effectual, but I have observed, that some of it passes undecomposed, in its oily form, through the intestines, and appears on the surface of the excrement, and, hence, may serve as a sort of sheather or defence to the diseased intestines, from the stimulus of fæces and morbid secretions."

‖ BALY—p. 535, *op. cit.*, p. 535, *supra;* COPLAND—Vol. I, p. 718, *op. cit.*, p. 682, *supra*.

¶ CHEYNE—p. 50, *op. cit.*, p. 686, *supra*—remarks that the combination with oil of turpentine was "borrowed from puerperal practice, and much used in Dublin;" that it rendered the operation of the oil milder and more certain, and that it "sometimes effectually reduced that tumefaction of the belly which often so much distressed the patient." BANKIER—p. 148 *et seq.*, *op. cit.*, p. 637, *supra*.

** BAMBERGER—S. 415, *op. cit.*, p. 578, *supra*—describes it as "das milder uber eben so sicher wirkende Oleum Ricini." VOGT—S. 178, *op. cit.*, p. 645, *supra*—enumerates it among the bland purgatives suitable for dysentery. SAVIGNAC—p. 363, *op. cit.*, p. 620, *supra*—remarks: "C'est le purgatif que j'emploie le plus volontiers dans la dysentéric." He adds that a small dose purges as well as a large one, which is therefore "complétement inutile:" he gives 10 to 12 grammes in broth or in an emulsion of almonds. NIEMEYER—Bd. II, S. 755, *op. cit.*, p. 645, *supra*—gave in the milder grades of dysentery a mild laxative, "am besten aus Ricinusöl oder Tamarindendecoct." HEUBNER—S. 545, *op. cit.*, p. 529, *supra*—observes: "Vor Allem ist hier das mild und sicher wirkende Ricinusöl hervorzuheben, dem in neuerer Zeit der Vorzug gegeben wird."

†† G. B. WOOD—Vol. I, p. 720, *op. cit.*, p. 671, *supra*—commended calomel as the cathartic par excellence in dysentery, but "as it is not quick in its operation" it should be "assisted by other medicines." * * * "Of these, castor oil is on the whole probably the best. Should it offend the stomach in its ordinary form, it may be administered in emulsion with gum arabic, sugar, and some aromatic water. In the advanced stages of dysentery, this oleaginous mixture may often be advantageously combined with a little laudanum, and given in small divided doses at short intervals. Thus administered, it often produces a soothing effect on the bowels, while it operates as a laxative." STILLÉ—*loc. cit.*, p. 707, *supra*.

‡‡ In Section II it is spoken of with favor by SCHÜSSLER—p. 44, *supra;* COUES—p. 64, *supra;* WAINWRIGHT—p. 78, *supra;* FORBES—p. 82, *supra;* PECK—p. 86, *supra;* BEACH—p. 89, *supra;* MORSE—p. 92, *supra;* HUNT—p. 94, *supra;* and BRADT—p. 100, *supra*. Some of these gentlemen combined it with laudanum, but most of them with oil of turpentine. See also, in favor of its use, the papers of P. C. PEASE—*op. cit.*, last page; J. F. HAMMOND—*op. cit.*, p. 697, *supra*—who used it after giving a scruple of calomel; W. KEMPSTER—*op. cit.*, p. 493, *supra*—who administered it with laudanum and ginger in diarrhœa from irritating food; JEHU LITTLE—*op. cit*, last page; and especially A. A. Surgeon HENRY M. LYMAN—*On the value of local treatment in chronic diarrhœa and dysentery*, The Amer. Med. Times, Vol. VIII. 1864, p. 149.

four years of the struggle.* Yet in England, where it first found favor, it seems to be losing credit in this disease. Aitken† does not appear to regard it as worthy of mention in this connection, and Maclean only refers to it incidentally as useful in some cases of mild dysentery.‡

Notwithstanding the array of testimony in its favor, I cannot say that the use of castor oil as a purgative in dysentery commends itself to my judgment. Not only is it objectionable on account of the extreme repugnance with which it is swallowed by the great majority of patients, its tendency to produce unpleasant gripings, which is so well known that the admixture of laudanum is usually resorted to as a matter of course, and the readiness with which it becomes rancid when kept on hand; but I am by no means satisfied by the evidence brought forward that it approaches other less objectionable cathartics in the efficacy of its action in this disease. Some of the most observant practitioners who have employed it report that it often fails to relieve the symptoms, or actually appears to aggravate them.§ The experiments of Rutherford and Vignal show quite positively that it exercises no stimulating action on the hepatic secretion,|| and it therefore fails to meet one of the most important indications in the early stages of dysentery. Of course it is not to be denied that its purgative action may be followed by benefit in conditions for which purgatives are appropriate; but better results may be obtained by other means. It seems strange to find the use of this nauseous oil in dysentery commended by some of those who have most urgently protested against the administration of even the blandest fats as food in this disease.¶ For myself, I have long since abandoned it, and counsel others to do the same.**

Calomel, which, during the early part of the present century, played so prominent a part in the treatment of dysentery, appears to have been first used for that purpose by Andreas Libavius about the commencement of the seventeenth century.†† Robert Boyle, having successfully treated an obstinate case of dysentery by calomel and rhubarb, communicated his treatment to a certain ancient army surgeon, who replied that calomel had been his own great arcanum in that disease, and that he had cured hundreds of soldiers with it.‡‡ Degner relates that during the reign of the pathologia animata calomel was

* See note †, p. 708, *supra*. † AITKEN—*op. cit.*, p. 647, *supra*.

‡ MACLEAN—Vol. I, p. 119, *op. cit.*, p. 657, *supra:* "In some cases it may be necessary to give a few drachms of fresh castor oil, guarded by a few minims of tincture of opium, or a few drops of chloroform."

§ For example, AUSTIN FLINT—*Clinical report on dysentery*, Buffalo Med. Jour., Vol. IX, 1853-4, p. 199—gave it in eight cases of dysentery. In two the disease appeared to be aggravated; in three no obvious change for the better or worse was observed; only in three was the apparent effect good, as indicated by the improvement in the character of the discharges.

|| RUTHERFORD and VIGNAL—Vol. X, p. 293, *op. cit.*, p. 701, *supra*. ¶ See note ‡, p. 668, *supra*.

** In so doing I have not overlooked any of the recent utterances in its favor. See, for example, H. C. WOOD—p. 433, *op. cit.*, p. 675, *supra:* "In various inflammatory or irritative affections of the alimentary canal, castor oil is of the greatest service, partly, no doubt, by removing acrid irritating secretions or foreign materials, such as undigested food, and partly by causing a depletion of the congested vessels, but also apparently by virtue of an almost specific power, which renders it the most satisfactory cathartic in these cases. This is especially seen in the acute diarrhœas and even in the chronic enteritis of children, but also holds good in the diarrhœas and dysenteries of adults."

†† This statement is made by C. OTTO, to whose elaborate dissertation—*De actione hydrargyri medica*, Part. I et II, Copenhagen, 1819—I refer the reader for the history of the mercurials generally, and of their use in various diseases prior to the date of this work. He remarks: "Usus mercurii in dysenteria admodum antiquus est, jam a Libavio commendatus, postea maxime a medicis Anglicis laudatus," Part. II, p. 174; and cites J. HORNUNGUS—*Cista Medica*, Nuremburg, 1625. This work I have not been able to see; according to MANGETUS—*Bibl. Script. Med.*, Geneva, 1731, T. I, Pars 2, p. 753, and T. II, Pars I, p. 77—it contains a number of the medical epistles and concilia of LIBAVIUS, who died 1616.

‡‡ ROBERT BOYLE—*The advantages of the use of simple medicines*, 1686; I cite *Works*, London, 1772, Vol. V, p. 119—remarks: "I remember, I had an opportunity to observe the efficacy of *mercurius dulcis*, in a stubborn dysentery, that had baffled the remedies of an ancient physician. But though a reflection on the virtue I knew this medicine to have of allaying sharp humours, and resisting putrefaction, may justly increase my favourable opinion of it; yet not thinking my experience competent, I imparted it to an ancient and expert chirurgeon, that was the chief of those, that belonged to a famous and judicious general of an army; who thereupon frankly confessed to me, that this was his great arcanum, wherewith he had cured many scores, or rather hundreds of soldiers in this general's army; only, whereas my way is to give from 8, or 10, to 12, or at most 15 grains of *mercurius dulcis* for a dose, made up with some little rhubarb, &c., or other ingredient that would make it work once, twice, or thrice with another patient, (for the dysentery itself helps to carry off the medicine;) he, both to disguise it, and to make it more easily takeable, made it up with sugar and mucilage of gum-dragon into lozenges, whereof one might contain from near a scruple to half a drachm of the *mercurius dulcis*, of which he ordered the soldiers to take one at a time, without hindering their march, only bidding them have a great care, that nothing should stick between their teeth, or in their throats."

regarded as an infallible antidysenteric by many of the physicians who believed the disease to originate from minute vermiculi.* Hoffmann protested against its use on theoretical grounds which appear to have convinced Degner,† but did not interfere with the gradual spread of the use of calomel in dysentery during the eighteenth century. In the dysentery of Minorca, Cleghorn sometimes gave six or seven grains of it at night, followed by a saline cathartic next morning.‡ The combination of calomel and rhubarb was commended by Richard Mead for dysenteries rendered obstinate by a bad habit of body;§ and the same combination was employed as a purge in the early stages of ordinary dysenteries by Pringle, Macbride, Geach and Hunter.‖

This use of calomel as a cathartic is a very different matter from the employment of it or other preparations of mercury with a view to producing the constitutional impression of the drug as expressed by salivation; but the history of the two modes of administering mercurials is so intimately connected that it will be convenient to consider both in this place. When Bogue visited India in 1772, he found it a common practice on the Coromandel coast to treat bilious and chronic fluxes with mercurial inunctions, or small doses of mercury frequently repeated.¶ This plan was brought to the notice of the profession in England in 1787 by Lind, who explained its alleged success by the supposed antiphlogistic power of the drug;** Thomas Houlston had previously published an account of several cases of dysentery successfully treated by mercurial inunctions pushed to salivation.††

---

* DEGNER—p. 236, note, *op. cit.*, p. 625, *supra:* "Mercurium dulcem jam ante multos annos plures medici tanquam non fallens medicamentum antidysentericum laudaverunt, dum putabant hunc morbum per vermium insecta excitari originemque ducere," &c.

† HOFFMANN—T. III, p. 157, *op. cit.*, p. 681, *supra:* "Unde non mirari satis possum, quosdam, et præsertim Boyleum de S. M. V. pag. 52. mercurium dulcem in dysenteria commendare: quippe qui ejus est indolis, ut ab admixtione salium acriorum, quæ in nostro morbo larga præsto sunt quantitate, causticus reddatur." DEGNER repeats this suggestion in the note just cited as an objection to the use of calomel in dysentery, and adds that it would be well to wait till the dysentery producing vermiculi are demonstrated before basing our therapeutics upon such a notion. I may add that BAKER—p. 29, *op. cit.*, p. 437, *supra*—expressed the opinion that it was better to give a larger quantity of rhubarb than to admix calomel as some recommend.

‡ CLEGHORN—p. 252, *op. cit.*, p. 637, *supra*—only administered it "when other means have failed:" he combined it with a grain of opium, and gave next morning the "purging apozem" described in note ‖, p. 706, *supra.*

§ RICHARD MEAD—*Monita et Præcepta Med.*, London, 1751; I cite the English translation published in London the same year: "Lastly I recommend as an useful remark, that this course is sometimes rendered ineffectual by a bad habit of body. In such cases, to the foregoing method it will be proper to add medicines, which correct the humors; and indeed some doses of rhubarb, with a small proportion of dulcified mercury sublimate, commonly called calomel, will prove very conducive to that end," p. 125.

‖ STILLÉ—*Therapeutics*, &c., 4th Ed., Philadelphia, 1874, Vol. II, p. 709—falls into a strange error with regard to PRINGLE, remarking: "The benefits of mercurials in this affection are said to have been first pointed out by Pringle, in 1768." The fact is, that not merely had others used this treatment for more than a century, but PRINGLE had already commended it in the 3d edition of his *Obs. on the Dis. of the Army*, London, 1761, p. 240, note, remarking: "By later experience I am convinced that rhubarb alone, in whatever dose, seldom operates so easily or so efficaciously, as when joined with well prepared calomel. My usual formula is that of the Pharmacop. Pauper. Edinburg, viz: ℞. Rhubarb. pulv. gr. xxv. mercur. dulc. sexies sublimat. gr. v. syr. simp. q. s. ut f. bol. mane sumend. But this medicine I never give in the very low state of the disease, when there is a putrid fever, or when I suspect the intestines to be much excoriated." In the 4th edition, London, 1764, p. 272, and in subsequent editions, this note is omitted, and a purge of "five grains of calomel, with five and twenty of rhubarb" strongly commended in the text. MACBRIDE—*loc. cit.*, p. 705, *supra.* GEACH—*loc. cit.*, p. 705, *supra.* J. HUNTER—*loc. cit.*, p. 709, *supra.*

¶ BOGUE, of Titchfield, communicated his observations to LIND, by whom they were published in his *Essay on Diseases incidental to Europeans in Hot Climates;* I cite 5th Ed., London, 1792, p. 99, note. This note was copied by CLARK—*vide* p. 712, *infra*—which has led EWART—p. 347, *op. cit.*, p. 681, *supra*—into error, for he attributes to him the observation of BOGUE. I may add that WILLIAM WRIGHT, in a letter dated December 10, 1794—*Med. Facts and Obs.*, Vol. VII, London, 1797, p. 24—claims to have given calomel freely (in doses of 5 grains every six hours) in dysentery as early as 1764.

** JAMES LIND—*An account of the efficacy of mercury in the cure of inflammatory diseases, and the dysentery*, (a letter dated Jan. 3, 1787,) The London Med. Jour., Vol. VIII, 1787, p. 43—states that this practice was "made known to the different surgeons in the Carnatic by a letter sent to each of them from the late Mr. Paisly, first surgeon of the Presidency of Madras. Their method is as follows:—As soon as the patient begins to complain of symptoms of dysentery, they give him repeatedly small doses of emetic tartar till it operates upwards and downwards, and thoroughly clears the stomach and bowels; after which they begin to give mercury combined with ipecacuanha in the following form: ℞. Argent. viv. ʒj. Pulv. gum arabic ʒij. Aq. puræ q. s. Tere in mortar. marmor. ad perfect. extinct. globulorum, et adde Pulv. rad. ipecacuan. ʒj. Fiat massa dividenda in pilulas clx., quarum capiat unam, tertia vel quarta quaque hora." LIND remarks: "It is probably from mercury preventing inflammation, and consequently mortification, that the above practice is successful;" and adds: "In the cure of inflammatory disorders by means of mercury, we ought carefully to guard against inducing any great degree of salivation, by which many dreadful symptoms are brought on."

†† THOMAS HOULSTON—*Obs. on Poisons; and the Use of Mercury in the Cure of Obstinate Dysenteries*, London, 1784; I cite the new Ed., Edinburgh, 1787, p. 63 *et seq.* The first of the cases is reported to have been thus treated in 1777. This method was also commended by WM. BOAG—*Obs. on the fevers and dysentery of hot climates; and on the use of mercury in those diseases*, Med. Facts and Observations, Vol. IV, London, 1793, p. 15—who states that when he wrote, Jan. 16, 1792, the usual method of treating those complaints in the general hospital at Bombay was "to rub two drachms of the strong mercurial ointment upon the belly, legs, and thighs of the patient, every night and morning, till it sensibly affects the mouth." The same plan was recommended by THOMAS THOMSON—*De la dysenterie, et des effets du mercure*, &c., Paris Thesis, No. 321, 1815, p. 10—who rubbed into the abdomen of the patient one or two drachms of mercurial ointment daily, and at the same time gave internally two grains of calomel, with half a grain or a grain of opium, two or three times a day until the mouth was affected; and as late as 1839 by CORNUEL—p. 136, *op. cit.*, p. 615, *supra*—who, however, only resorted to it in very severe cases of acute dysentery, because in slight or chronic cases he found it so apt to salivate.

Meanwhile Clark had employed repeated doses of calomel and opium in the epidemics of dysentery which occurred at New Castle and its vicinity from 1781 to 1785; until the last of these epidemics he was in doubt whether the apparent benefit was due to the purgative or the mercurial action of the medicine, but he then became convinced that the latter view was correct, and claimed that so soon as the gums became tender the gripes and tenesmus were relieved and the patient promptly recovered.*

The administration of calomel and opium with a view to salivation soon became a favorite mode of treating dysentery in India, if we may judge from the accounts of cases treated in the Calcutta General Hospital in 1796 and 1797, preserved by Charles Maclean and Alexander Grant. If four to ten grains of calomel combined with one to six of opium, and frequently repeated, did not salivate, free inunctions with mercurial ointment were employed to hasten the effect. The deplorable mortality that resulted did not disabuse the minds of the Indian practitioners of their blind confidence in the wisdom of the plan they had adopted.† We have the testimony of Johnson with regard to the employment of calomel in large doses pushed to salivation by various English naval surgeons during the first decennium of the present century. Among them, Cunningham, in 1805, gave it in scruple doses, repeated twice or thrice a day; one of his patients took in this way eighteen scruples: he claimed that of sixty patients thus treated none died. Johnson himself employed the same mode of treatment, but only in cases of emergency; in ordinary dysenteries he was content to give daily in divided doses from twenty-four to forty-eight grains of calomel with from two to four grains of opium and ten to fifteen of antimonial powder or ipecacuanha. His object in either case was the prompt production of salivation; for he held that nothing could be more useful, after the first stage of the disease had been treated by free venesection, than to saturate the system with mercury.‡ Salivation, indeed, appears to have been the object of most of the English physicians who gave calomel, whether in

* JOHN CLARK—Part II, Chap. 3, Sect. 4, "*On the treatment of obstinate dysenteries by mercury,*" p. 230 *et seq.*, *op. cit.*, p. 709, *supra*. Twelve illustrative cases are given, all selected from the epidemic of 1785. He cites the observations of BOGUE and the paper of LIND, but remarks: "Although mercury had not been proposed for the cure of the dysentery when I was last in India, yet it appears that, soon afterwards, its efficacy was confirmed in this disease. But, having had no correspondence with my acquaintances in that part of the world, this circumstance did not come to my knowledge till the year 1787," &c., p. 258. As to the mode in which he thought the remedy acted, see p. 232. He gave at the beginning of the disease, every night, 5 to 10 grains of calomel with enough opium "to procure an alleviation of the gripes;" after a few nights he diminished the quantity. To two patients he gave 3 grains of calomel conjoined with opium every four hours.

† CHARLES MACLEAN—*Practical Illustrations of the Progress of Medical Improvement for the last thirty years*, London, 1818. See cases 16, 17, 18, 20 and 22, p. 48 *et seq.*, all treated in the General Hospital, Calcutta, in 1796. A. GRANT—*op. cit.*, p. 691, *supra*—has preserved a dozen cases similarly treated in the same hospital in 1797. WALTER RALEIGH—*Obs. on Idiopathic Dysentery*, Calcutta, 1842, p. 61—examined some of the diaries of this hospital, "which the white ants had not entirely eaten up," and reports that during the years 1797, 1798 and 1799 he found the records of 238 cases of dysentery treated, of whom 127 died. He justly remarks: "Such frightful extent of mortality may doubtless in part be attributed to the inefficient or even baneful treatment pursued for the relief of the disease, at these early periods," p. 63.

‡ JAMES JOHNSON—p. 218 *et seq.*, *op. cit.*, p. 682, *supra*. He gives a tabular view of thirty cases treated by JOHN CUNNINGHAM, surgeon of H. M. S. Sceptre, (on board that ship,) in 1805. The average number of scruples of calomel taken by each man was seven and a half. CUNNINGHAM is cited as saying "that calomel, administered in scruple doses twice or thrice a day, is an almost certain remedy for dysentery—in hot climates at least," and that "in obstinate cases, the system must be well impregnated, before a permanent cure can be expected," p. 222. JOHNSON himself spoke of his ordinary method described in the text as giving "mercury, in comparatively small doses," p. 218, and further on remarks: "But whenever, in doubtful cases, I had occasion to push boldly on for ptyalism, I gave the calomel in scruple doses; which I found, by repeated experience, to sit easier than either a smaller or a larger quantity of that medicine—a curious, but a certain fact." See also p. 235. The American reader will be interested to learn from an article on the *Medical topography of New-Orleans; with an account of the principal diseases that affected the fleet and army on the late expedition against that city*—communicated by a Naval Surgeon, The Edinburgh Med. and Surg. Jour., Vol. XII, 1816, p. 136—that the English army, defeated by General Jackson, before New Orleans, January 8, 1815, had previously suffered greatly from dysentery, which was treated with calomel in scruple doses. The writer, whose patriotic hatred of the Americans is comically conspicuous in his account of the events of the expedition, was probably as formidable to the English army as any officer of equal rank on the American side, for he writes: "I have in this way given 16, 18, or 20 scruples of calomel in the course of half as many days, before the mouth became affected." Indeed so general did this plan of treatment become that CRAIGIE—Vol. I, p. 927, *op. cit.*, p. 268, *supra*—tells us that it was "emphatically named the scruple dose practice." STILLÉ—in the first edition of his *Therapeutics and Materia Medica*. Philadelphia, 1860, Vol. II, p. 833—makes the astonishing statement that "The treatment of dysentery by large and repeated doses of calomel appears to have originated with Annesley. (Diseases of India, p. 434 *et seq.*)" Now ANNESLEY himself, in the work cited, expressly states that he derived his plan of giving scruple doses of calomel from JOHNSON: see note ‡, next page. The same misstatement will be found in the 3d edition of STILLÉ'S work, Philadelphia, 1868, Vol. II, p. 716, but in the 4th edition, Philadelphia, 1874, Vol. II, pp. 799 to 801, "AINSLIE" is in several places substituted for "ANNESLEY;" an evident misprint. Indeed, I note that AINSLIE—*Materia Indica*, London, 1826, Vol. I, p. 649—so far from having invented the plan of giving large doses, which he attributes to ANNESLEY, CARTWRIGHT and others, preferred "repeated small doses, by which means I found the weapon more within my own control;" and again, on p. 553, declares that he "certainly would object to the very large doses now given equally in England and in India ever being introduced into general practice."

large doses or small, during the first quarter of the present century; they hoped in this way to obtain to the utmost the supposed antiphlogistic virtues of the drug.*

There were a few who, like Bampfield and Ballingall in India, and Cheyne in Dublin, sought to impose some limitations on these excesses.† With these undoubtedly should be ranked Annesley, who indeed gave calomel in scruple doses as a purge, and in smaller doses to act upon the liver, yet insisted that the production of ptyalism should not be made the object of the physician. But the plausible manner in which Annesley maintained the cholagogue and antiphlogistic virtues of calomel, and his bold assertion, that if ptyalism does occur it should be viewed as a satisfactory indication of the beneficial operation of the treatment, had probably more influence in encouraging the free use of this mercurial than his warnings exercised in the direction of restraint.‡ Certainly calomel in scruple doses, or calomel or other mercurials pushed to salivation, continued for some years to be freely employed in India, as may be seen by the testimony of Waddell, Bankier, R. H. Hunter, Green, Moffat and Raleigh.§

* Among those who used this practice I may name Sir JAMES MCGRIGOR—*Med. Sketches of the Expedition to Egypt from India*, London, 1804, p. 185: "Mercury is now the remedy relied on everywhere." Neutral salts may sometimes be substituted in acute cases, but "when the disease was of some weeks standing, and where a chronic disease occurred, calomel given in small doses proved the best and indeed the only useful remedy." Subsequently he came to restrict the applicability of mercury to cases in which there is some hepatic complication; and thought it advisable to "introduce it gradually and gently into the system," but he still held that "the cases are very numerous, where no other remedies gave the patient a chance of life," p. 431 *et seq.*, *op. cit.*, p. 612, *supra*. WILLIAM FERGUSON—*On the mercurial plan of treatment in dysentery*, (read Jan. 16, 1810,) Med.-Chir. Trans., Vol. II. 2d Ed., London, 1817, p. 181—advised that "half a grain of calomel, with one grain of ipecacuan," should be given every hour, "till the gums were affected. This generally took place in 48 hours, when a solution of the disease might be looked for with confidence," p. 184. CHISHOLM—p. 60, *op. cit.*, p. 396, *supra*—gave in hepatic dysentery 3 grains of calomel, 4 grains of ipecac. and half a grain of opium every three hours. When the danger was imminent, "the dose of calomel was augmented in such manner as to excite ptyalism as quickly as possible. When this took place, danger ceased, and the patient soon became convalescent." This mode of treatment he tells us he first began to use in the year 1786. LATHAM—p. 62 *et seq.*, *op. cit.*, p. 439, *supra*—who sometimes gave large, sometimes small, doses, writes: "Our ultimate object, in all cases, was to produce salivation," p. 72; and this notwithstanding his belief in the scorbutic nature of the disease.

† BAMPFIELD—p. 134 *et seq.*, *op. cit.*, p. 682, *supra*—although he dissented from the opinion that mercurials possess "the exclusive power of curing dysentery," used calomel freely enough both as a purge and for its constitutional impression. He even admitted the desirability of pushing the medicine to salivation—p. 138—but declared it "an object worthy of attention, to avoid the excitement of an unnecessarily profuse degree of ptyalism." BALLINGALL—p. 73, *op. cit.*, p. 682, *supra*—discountenanced the use of calomel in acute dysentery, but strenuously urged its employment in the chronic forms—p. 80—in which he regarded it "as a *sine qua non* in the cure;" yet he strongly protests against "the profuse salivations, which many suppose necessary." CHEYNE—p. 44, *op. cit.*, p. 686, *supra*—always laid aside the mercurial when ptyalism was recognized, and declared that "when the disease, as we conceived, had attained the ulcerative stage, mercury, which was given on the authority of Clarke, was injurious."

‡ ANNESLEY—Vol. II, p. 287, *op. cit.*, p. 621, *supra*: "Mercury, when given, either in simple or complicated dysentery, late in the disease, with a view of affecting the system, or when its exhibition is continued with this intention for too long a period, often seems to precipitate the malady to an unfavourable termination, by inducing or keeping up irritative fever, and by lowering the powers of life." And again: "Endeavours to excite ptyalism by too frequent and too long an exhibition of mercury, are generally most pernicious," p. 290. But he adds that it should "be viewed, when it does occur, as a satisfactory indication of the beneficial operation of this treatment, and of the removal of the disease." In an earlier work—*Sketches of the most prevalent Diseases of India*, London, 1825, Part III, *Practical obs. on the effects of calomel on the mucous surface and secretions of the alimentary canal; and on the use of this remedy in disease, more particularly in the diseases of India*—ANNESLEY relates—p. 383—that he had given calomel only in moderate doses until he perused the work of JOHNSON, which induced him to try scruple doses. His success led him to advise in acute dysentery the administration of a scruple of calomel at bed time, followed by a purgative draught next morning, p. 437; after which he often directed three grains of calomel with three or four of ipecacuanha, and one of opium, to be taken three times a day, "to act upon the skin, and upon the liver, through the medium of a partial absorption;" but he says: "Care must be taken not to continue the remedy until it shall affect the mouth, which ought not in any case to be made sore by it," p. 438. In the same treatise he relates—p. 389 *et seq.*—certain experiments performed on dogs with large doses of calomel. These, he thought, showed that the effect of the drug was to diminish the vascularity of the mucous membrane of the stomach and intestine, and hence that its operation "is directly the reverse of inflammatory," p. 397. He also believed, from the effects observed when calomel is admixed with the tenacious mucus frequently found coating the intestinal mucous membrane in the dead human subject, that calomel administered during life renders the tenacious mucus formed there in disease more fluid, and suggests: "May not its operation upon this secretion in the duodenum be the means of removing such obstruction from the common duct, as this secretion may be considered to occasion; and thus it may effect a discharge of bile into the intestine, which was only prevented by the mechanical obstruction placed in its way," p. 399. He held further that small doses of calomel often repeated "will become absorbed," and "thus act immediately on the liver." They may thus cause distension of the gall-bladder which a purge of calomel will be required to relieve, p. 401. These speculations were long regarded as established facts by the majority of English, and I may add of American, physicians.

§ G. WADDELL—*On the diseases which prevailed among the British troops at Rangoon*, Trans. of the Med. and Phys. Soc. of Calcutta, Vol. III, 1827, p. 257—used scruple doses of calomel, and aimed at salivation either by the internal use of this drug or by frictions with mercurial liniment. JAMES BANKIER—p. 209 *et seq.*, *op. cit.*, p. 637, *supra*—strongly defended the use of scruple doses of calomel—p. 213—which he believed to exert a decidedly sedative effect—p. 227. As for the chronic cases, he held that "we never can in general depend on a complete cure unless we touch the gums, which shews the system fully under the influence of the remedy, and in general we are not safe until this be accomplished," p. 251. R. H. HUNTER—*Annual report of the diseases of H. M. 2nd or Queen's Royal Regiment*, (for 1837-8,) Trans. of the Med. and Phys. Soc. of Bombay, Vol. II, 1839, p. 32—used mercury in scruple doses; also used it to salivation. W. A. GREEN—*Howrah hospital report. Remarks of* 1837-38-39-40, Trans. of the Med. and Phys. Soc. of Calcutta, Vol. VIII, Part II, 1842, p. 173—did the same, remarking: "Salivation, when occurring after full and sufficient bleeding, I have generally found a favorable sign, not that I would aim at salivation as a means of curing the disease," p. 182. J. W. MOFFAT—*Med.-hist. abstract of the first year's service in the East Indies of H. M.'s 14th reg. of light dragoons*, Trans. of the Med. and Phys. Soc. of Bombay, No. V, 1842, p. 141—obtained the mercurial impression by small doses repeated "till the system come under its influence;" this he believed to be "the safeguard" in dysentery. W. RALEIGH—p. 72, *op. cit.*, last page—declared "that for the cure of acute dysentery the ipecacuan treatment is not worthy of that confidence which the mercurial treatment is fully entitled to."

But more moderate counsels gradually began to prevail. Already, in 1829, Twining preferred blue pill to calomel, and thought sufficient assistance could be obtained from either without producing salivation. In 1841 Macpherson earnestly denounced the injudicious manner in which calomel had been used in India, and expressed the opinion that milder measures ought to be employed. In the same year Murray, repeating the experiments of Annesley on a larger number of dogs, showed that erroneous conclusions had been arrived at in several respects, and demonstrated that considerable doses of the drug act as a direct irritant to the gastro-intestinal mucous membrane. Ewart expresses the opinion that these experiments exercised considerable influence in favor of moderation in the use of mercurials; be this as it may, we find already, in 1844, the declaration of Morehead that the use of large doses of calomel and the production of salivation were no longer common in the treatment of dysentery in India. It is, however, worthy of note that all these writers themselves employed calomel or blue pill, in what they were pleased to consider moderate quantities, both as cathartics and in small repeated doses, and attached much importance to this mode of treatment,* which is also spoken of approvingly in the treatise of Parkes and the later works of Morehead and Martin.† The general introduction

* TWINING—*loc. cit.*, p. 695, *supra*. In Vol. I, p. 70 *et seq.*, *op. cit.*, p. 698, *supra*, the same views are repeated. He combined the blue pill in five-grain doses with his ipecacuanha and gentian. Sometimes, however, he used calomel in the same way. A similar preference for blue pill is expressed by H. H. GOODEVE—*On the treatment of dysentery*, Trans. of the Med. and Phys. Soc. of Calcutta, Vol. VI I, Part II, 1842, p. 476—who writes that it is "equally powerful with calomel, in correcting the secretions, bowels and in producing a healthy action of the liver; and it does not in these cases irritate the alimentary canal in the same degree as the chloride of mercury." J. MACPHERSON—*Notes on some points of Indian practice*, The London Med. Gaz., Vol. XXVIII, 1841, p. 548—writes: "It cannot admit of a doubt that calomel and drastic purgatives have been most injudiciously used in this disease, and that a return to a milder mode of treatment will be attended with the most beneficial results." Yet he adds: "The combination of blue pill, ipecacuanha, gentian, and hyoscyamus, so commonly employed, is a most useful preparation." J. MURRAY—*Expts. illustrative of the physiological effects of calomel on the gastro-intestinal mucous membrane of dogs*, Trans. of the Med. and Phys. Soc. of Bombay, No. IV, 1841, p. 1—found that the administration of calomel to healthy dogs produced increased vascularity of the gastro-intestinal mucous membrane resembling, in the large intestine, the appearances observed in cases of acute dysentery—p. 16. The degree to which this condition was developed was greater in proportion as the dose was larger. It was "slightly marked after doses of five and ten grains," and "becomes more perceptible in doses of twenty and thirty grains, and is accompanied with more or less sanguineous effusion on the mucous surface, either in dots (like bleeding points) or in small streaks or patches." In doses of one to three drachms it produces, in addition, "capilliform injection of the peritoneal coat of the stomach and bowels," p. 12. He pointed out the error of the opinion of ANNESLEY, that the healthy state of the stomach and bowels is one of high vascularity, and repudiated the sedative effect which that observer attributed to large doses of the drug; yet agreed with him in believing that calomel increases the flow of bile into the duodenum, a conclusion at which both appear to have arrived solely from inspection of the intestinal contents and the stools. MURRAY also held that the drug "increases the secretion from the intestinal mucous follicles and serous exhalants," *loc. cit.* In a subsequent paper—*Obs. on the good and bad effects of calomel in some of the diseases of India*, same Transactions, No. V, 1842, p. 145—he maintained that calomel may be advantageously given in the early stages of dysentery, at considerable intervals, in 10 grain doses, (which he calls "full doses,") combined with two or three grains of opium. At a later period he thinks preference should be given to blue pill in small doses, also combined with opium. EWART—p. 363, *op. cit.*, p. 681, *supra*—remarks of MURRAY'S experiments: "They must have exercised considerable influence in deterring physicians from having recourse to the gigantic doses prescribed by Johnson, Annesley, and their disciples." C. MOREHEAD—*Notes on the pathology and treatment of dysentery as observed in the European gen. hosp. at Bombay during the five years from July*, 1838, *to July*, 1843, Trans. of the Med. and Phys. Soc. of Bombay, No. VII, 1844, p. 156—wrote: "The treatment of dysentery by large doses of calomel repeated and continued for some time, on the principle that such doses have a sedative action on the inflamed mucous coat, does not I think at present find much acceptance in this part of India; and I believe that it may fairly be assumed that a system of treatment strongly recommended and at one time generally followed, as this has been, would not have fallen into disuse, unless the expectations formed of its efficacy and applicability had led to disappointment. On this principle I would explain the comparative infrequency of the treatment of dysentery by large doses of calomel repeated and continued for some time. My own belief is that as a general system of treatment it is inappropriate and very often very injurious." Yet the writer in the same essay advises that during the first two or three days of attacks of dysentery, if the constitution of the patient is not broken down by former disease or other cause, ten grains of calomel with a grain and a half or two grains of ipecacuanha, and the same quantity of opium should be given at bed time, followed next morning by from six drachms to an ounce of castor oil; this may be repeated twice or thrice, in accordance with the condition of the tongue, the character of the dejections and the degree of abdominal distention. As to the induction of the mercurial impression, he remarks: "I am not aware that recent writers are in favour of this course," p. 155. He thinks it might be useful if there is "considerable thickening of the walls of the large intestines" without ulceration, but it must be difficult or impossible to recognize this condition, so that "there is good reason for not recommending, as a general course, the treatment of dysentery by this means."

† PARKES—p. 142 *et seq.*, *op. cit.*, p. 682, *supra*—deprecated the induction of salivation, and pointed out its injurious effects, especially in adynamic or malignant dysentery, and in cases complicated by a scorbutic taint or by hepatic abscess. As to large doses, such as ANNESLEY commended, he wrote: "I have often seen profuse salivation produced, which Mr. Annesley professes to avoid. I have witnessed in many cases aggravation of the tenesmus, and increase of blood in the stools, and as calomel, in poisonous doses, in men and dogs, causes intense and hæmorrhagic congestion of the colonic and rectal mucous membrane, I am unable to conceive the therapeutical indications on which its use is founded." Yet even he favored the cautious use of mercury as an alterative, or as a substitute for depletion, for he adds: "For my own part I have ceased to use mercury in dysentery, in any other way than as an alterative, except in chronic and long protracted and recurrent acute cases. I never aim at ptyalism, and can confidently assert that my recoveries have been greater in number, and more complete, since I in a great measure abandoned the use of mercury, than when I gave it in large quantities. If, from any cause, depletion cannot be used, then, in common acute dysentery, mercury must be had recourse to, as the next most useful plan of treatment," p. 145. On p. 146 also he enumerates the "occasional production of salivation" among the "essential measures in the early stage of common acute dysentery." In at least one form of chronic dysentery also he declares that "mercury is really the most valuable medicine that can be used," p. 151. For this purpose he especially commends corrosive sublimate in doses of $\frac{1}{8}$ to $\frac{1}{6}$ of a grain combined with the preparations of cinchona. MOREHEAD—p. 296, *op. cit.*, p. 657, *supra*, in the second edition of his work, published in the year 1860—reiterates substantially the views advanced in the paper cited in the last note. He remarks, in almost the words of that paper: "The object in exhibiting calomel is to increase the secretion of the liver and of the mucous lining of the

of the ipecacuanha treatment in India has, however, since 1860, pretty generally crowded out the calomel fashion; it has fallen for the most part silently into disuse, although some practitioners, as for example Maclean, openly deprecate its employment in all stages and forms of dysentery.*

In the temperate climate of Great Britain the heroic doses of calomel advised by Johnson and Annesley never secured the universal confidence they so long enjoyed in India. The feeling was very general that this method was only appropriate for tropical dysentery, and that milder measures might be employed in England.† Yet although the publication of the experience of Roots, who found that in many instances of chronic dysentery calomel, even in combination with opium, appeared to increase the irritability of the bowel, was followed by the testimony of Baly, who sometimes observed similar results in acute cases,‡ these objections did not prevent the very general employment of small doses of calomel combined with opium and ipecacuanha, and repeated with a view to the alterative effect of the mercurial. Blue pill, or hydrargyrum cum creta, was sometimes used instead of calomel for this purpose. Baly himself approved this treatment, which was commended among others by Copland, Joseph Brown and Mayne,§ and has only passed out of general use in comparatively recent times.

Pills of calomel, opium and ipecacuanha have also, since 1834, enjoyed a certain degree of popularity in France, where they are often spoken of with national vanity as the "*pilules de Ségond.*" But Ségond himself never claimed the credit of this combination, which he honestly states he borrowed from the English physicians in Demerara, by whom he relates it was employed with considerable success.‖ Erhel found these pills serviceable in mild but not in grave dysenteries; Savignac was inclined to restrict them to chronic cases, and Barrallier affirms that even in these they are only sometimes useful.¶ The French physicians appear to have acquired a knowledge of the use of large doses of calomel

small intestine, but at the same time to be careful that it does not aggravate the existing inflammation of the large intestine. This latter injurious effect is to be guarded against by avoiding the frequent repetition of the calomel, and by combining it, when used, with opium." MARTIN—p. 441, *op. cit.*, p. 621, *supra*—not merely commended purgative doses (10 grains) of calomel combined with an equal quantity of James's powder or ipecacuanha, but thought it proper often to combine "some mild mercurial," such as blue pill or calomel, with the diaphoretics and diuretics subsequently administered; but he did not favor pushing it to ptyalism, and thought that mercury should not be used in any shape in the adynamic forms of the disease, or in the splenic cachexia, "for in all these conditions of the system its actions are most injurious," p. 458.

* MACLEAN—Vol. I, p. 124, *op. cit.*, p. 657, *supra:* "It will not fail to be remarked that I have not only not advised but by implication have deprecated the use of mercury in all stages and forms of the disease." He offers as reasons, besides the objections to ptyalism, and the superiority of the ipecacuanha treatment, &c., the important statements that "experience has shown that men 'cured' by mercurial treatment are as a rule cachectic, exsanguine, prematurely old-looking, extremely sensitive to atmospheric changes and to relapses from trivial causes;" and that "chronic dysentery is more frequent after mercurial treatment than when the disease is treated by ipecacuanha."

† Thus JOSEPH BROWN—*Dysentery*, The Cycl. of Pract. Med., Amer. Ed., Vol. I, Philadelphia, 1845, p. 726—writes: "It is a remedy more generally applicable to dysentery in warm latitudes than in this country."

‡ ROOTS—*Chronic dysentery*, St. Thomas's Hosp. Reports, Vol. I, 1836, p. 272. BALY—p. 536, *op. cit.*, p. 535, *supra.*

§ BALY—*loc. cit.*, last note. COPLAND—Vol. I, p. 731, *op. cit.*, p. 682, *supra.* JOSEPH BROWN—*loc. cit.*, note †, *supra:* "A grain or a grain and a half of calomel, combined with from five to ten grains of Dover's powder, or half a grain of opium; or five grains of hydrargyrum cum creta, likewise combined with the opiate; may in this country be administered at intervals of four hours, the period being lengthened when the symptoms begin to abate. It is not necessary to excite ptyalism, although this is a contingency from which no evil result need be apprehended, provided the medical attendant be sufficiently watchful of the effect of the remedy to prevent its being excessive." R. MAYNE—*Obs. on the late epidemic dysentery in Dublin*, The Dublin Quart. Jour. of Med. Sci., Vol. VII, 1849, p. 303: "Two grains of calomel, with three of Dover's powder, every fourth hour, usually succeed, even in the most acute varieties of the disease; and much smaller quantities, or even hydrarg. cum creta, or blue pill, have been sufficient in many cases." But he remarks: "I feel convinced that when the gums are once fairly affected by calomel its further exhibition does no good in dysentery."

‖ SÉGOND—p. 163, *op. cit.*, p. 695, *supra*—gives the English formula as employed in Demerara as follows: "Ils administrent (en 4 ou 5 fois dans les 24 heures), un mélange de 8 g. d'ipéca, 2 de calomel, et ½ de grain d'opium." He adds: "Le ptyalisme s'en suit presque toujours." Elsewhere—*Documents relatifs a la méthode éclectique employée contre la dysenterie*, Paris, 1836, p. 48—he recommends the following formula: "℞. Ipéca gr. viij, calomel gr. iv, extr. gom. d'opium gr. j, gom. arabique q. s. Faites six pilules, à prendre dans la journée de deux en deux heures." But he remarks in a foot note that the proportion of the several ingredients ought to vary according to the particular indications of each case. SAVIGNAC—p. 371, *op. cit.*, p. 620, *supra*—relates the manner in which SÉGOND'S name came to be attached to these pills, as follows: "Ségond, médecin en chef à la Guyane française, emprunta aux médecins de la colonie anglaise de Démérary une formule dont il proclama avec ardeur les vertus antidysentériques; les médecins de Cayenne, témoins des succès qu'il en obtint, y attachèrent son nom."

¶ H. D. ERHEL—*Étude sur la dysenterie*, Paris thesis No. 254, 1851, p. 57 *et seq.*—was of the opinion that ipecacuanha was most suitable for mild, and calomel for severe dysenteries; the pilules of Ségond he regarded as inefficient in serious cases. SAVIGNAC—*loc. cit.*, last note. BARRALLIER—p. 779, *op. cit.*, p. 603, *supra*—writes: "Nous pouvons le dire avec vérité, il résulte des travaux des médecins de la marine française et de notre expérience personnelle que la formule de Ségond ne convient qu'exceptionnellement dans la dysenterie aiguë et qu'elle est quelquefois utile dans l'état chronique."

in dysentery chiefly through reports of the success of the English army surgeon Amiel at Gibraltar in 1812.* Trousseau relates that Bretonneau and himself endeavored to emulate these results during the Touraine epidemic, but were obliged to abandon the method on account of the severe salivation sometimes produced. He was led ultimately to administer calomel only in the minute doses suggested by Robert Law, of Dublin, in 1839; but appears to have given these rather with a view to the purgative action of the drug than to the constitutional impression which Law aimed at obtaining in this way, and to have employed them, especially in the case of children, as a substitute for the saline purgatives which he preferred for adults.†

On the other hand, several of the French surgeons in Algeria claimed to have obtained beneficial results with calomel in purgative doses. Cambay gave a gramme at bed time combined with five centigrammes of opium, and followed next morning by a laxative, and claimed that he had successfully treated about two hundred cases in this manner.‡ Catteloup not only used purgative doses of calomel, but sometimes employed the "*pilules de Ségond*" in the subsequent treatment;§ and Haspel went so far as to give one or two grammes of calomel a day in combination with opium and ipecacuanha.‖ In like manner Savignac favored the use of calomel as a purgative in the inflammatory form of dysentery and whenever it was desired to increase the obstinately suspended hepatic secretion; he also revived the once famous combination of calomel and rhubarb.¶ Jaccoud commended the same plan of treatment, and declared that the efficacy of calomel in dysentery is truly marvellous.** So, too, Barrallier regarded purgative doses as useful not only in inflammatory cases, but whenever the stools are bloody or the disease severe.††

* I have not been able to see the original memoir of AMIEL, an abstract of which is given by F. P. E. MEUSNIER—*De la dysenterie épidémique*, &c., Paris Thesis No. 99, 1830, p. 24: "Mon ami M. le docteur Trousseau, professeur aggrégé à la Faculté de médecine de Paris, m'a communiqué un mémoire fort curieux de M. AMIEL, chirurgien-major du 12e régiment de ligne, actuellement en garnison à Gibraltar." He goes on to relate that dysentery was epidemic at Gibraltar in 1815, that AMIEL treated it with calomel in half-drachm doses, given morning and evening, for from three to six days, and that this treatment was so successful that it was adopted by the surgeons of all the other regiments at Gibraltar. TROUSSEAU himself—*loc. cit.*, next note—relates the same story, but makes the date 1812, and adds: "Le succès de la médication fut tel, que la direction générale du service de santé militaire en fit une loi absolue pour tous les autres médecins." So, too, in the *Traité de Thérapeutique et de Matière Médicale* of TROUSSEAU and PIDOUX, 3me Éd., Paris, 1847, T. I, p. 228, I find the treatment of dysentery with 2 grammes of calomel morning and evening mentioned, with the remark, "C'est à M. le docteur Amiel, chirurgeon-major du 12e régiment de ligne de l'armée anglaise, qu'est dû le mérite d'avoir le premier formulé d'une manière nette cette méthode de traitement." The date given in this work also is 1812. BARRALLIER—*loc. cit.*, next note—accordingly speaks of the use of large doses of calomel in dysentery as "méthode d'Amiel." This surgeon, however, does not deserve the credit or blame of having originated this method, which we have seen was in common use among the English naval surgeons before 1812, and, in view of its reputation in France, it is curious that I have found no reference to the memoir mentioned above in any English work.

† TROUSSEAU—T. III, p. 168, *op. cit.*, p. 664, *supra*—held that the action of calomel in dysentery was probably exclusively local and similar to that of the neutral salts. After relating the story of his earlier trials of this drug, he adds: "J'ai donné le calomel, *fracta dosi*, suivant la méthode de Law, c'est-à-dire 5 centigrammes (un grain) divisés en 10 paquets, qui étaient administrés d'heure en heure. Cette méthode de traitement m'a paru surtout avantageuse chez les enfants, auxquels il est souvent difficile de faire accepter les purgatifs salins." ROBERT LAW—*Obs. on the exhibition of mercury in minute doses*, The Dublin Jour. of Med. Sci., Vol. XIV, 1838-9, p. 393—insisted particularly upon "the very small quantity of mercury required to affect the system, when exhibited in minute doses at short intervals." He gave hourly $\frac{1}{12}$ of a grain of calomel made into a pill with extract of gentian. From two to four grains administered in this way salivated. Under the name of "méthode de Law" the procedure above described by TROUSSEAU is mentioned by SAVIGNAC—p. 369, *op. cit.*, p. 620, *supra*—who, however, prefers to administer hourly four or five times the quantity, as less likely to salivate; and by BARRALLIER—p. 778, *op. cit.*, p. 603, *supra*—who remarks: "Aussi la méthode de Law, qui peut être conservée dans le traitement de la dysenterie des enfants, est-elle aujourd'hui repoussée par presque tous les médecins chez les adultes."

‡ CAMBAY—p. 569 *et seq.*, *op. cit.*, p. 550, *supra*. § CATTELOUP—p. 132 *et seq.*, *op. cit.* p. 618, *supra*.

‖ HASPEL—T. II, p. 125, *op. cit.*, p. 621, *supra*—gave, with one or two grammes of calomel, from six decigrammes to a gramme of ipecacuanha and ten or twelve drops of laudanum. He writes: "A l'aide du protochlorure de mercure employé au début de la dysenterie, si les malades n'ont pas fait de grandes pertes de sang, je suis parvenu à juguler des dysenteries qui auraient pu devenir très graves."

¶ SAVIGNAC—p. 365 *et seq.*, *op. cit.*, p. 620, *supra*—writes that in his early practice he used calomel freely, but the inconveniences resulting from its use and its frequent insufficiency have led him to limit its employment greatly. In the cases indicated in the text he thinks its purgative action useful, but he regards its alterative action profitless. He gives a gramme at a single dose, or divided into three or four parts, which are taken at intervals of quarter or half an hour; or he administers 20 to 30 centigrammes divided into powders of 25 milligrammes each, one of which is taken every hour. This latter method he calls "la méthode de Law modifiée:" see note †, *supra*. Finally, he employs sometimes the following: "Calomel, 50 centigrammes; rhubarbe, 2 grammes; opium, 3 à 5 centigrammes,—pour 15 pilules, que je donne à doses rapprochées ou filées, selon les cas."

** S. JACCOUD—T. II, p. 340, *op. cit.*, p. 649, *supra*—gives the calomel solely for its purgative effect, and prefers to the "méthode de Law" the administration of a gramme and a half to two grammes at a dose, repeated if necessary morning and evening; or a gramme or two of calomel divided into ten powders, one to be taken every hour.

†† BARRALLIER—*loc. cit.*, note †, *supra*: "Entre les éloges outrés adressés au calomel par un grand nombre de médecins anglais et les appréciations sévères de Morehead, il y a un juste milieu qu'il est important de suivre. Ce médicament est utile lorsqu'on constate la présence d'un état d'éréthisme inflammatoire, lorsque les selles sont sanglantes et dans tous les cas où la dysenterie offre un notable degré de gravité."

In Germany purgative doses of calomel in dysentery were recommended as early as 1793 by Richter, who declared that he knew no other purgative at once so powerful and so gentle in its action. It would appear, also, from his posthumous work on Special Therapeutics, that he sometimes gave at bedtime a combination of a grain each of calomel, opium and ipecacuanha for its diaphoretic action.* Since his time both large and small doses of calomel have had their partizans in Germany. The former have been advocated, among others, by Kreyssig, Hauff, Rösch, Siebert, Berndt, Schweich and Canstatt.† Smaller doses, pushed to salivation, were commended in 1834 by Eisenmenger, who relates that he learned this method from a friend who had practiced medicine in Batavia. He gave every three hours a pill containing one grain of calomel, two of ipecacuanha and quarter of a grain of opium, and claimed that after salivation occurred the symptoms rapidly subsided. This method had some vogue for a time, and is mentioned with approval by Naumann and Hauff.‡ Bamberger, on the other hand, appears to have regarded the use of large doses of calomel with distrust, for he writes that he had no such personal experience of their effects as would justify the expression of an opinion. The action of small doses, generally combined with opium, he observed quite frequently; often a favorable result followed, but it was not more striking than the results which were observed as often after other treatment, and sometimes stomatitis mercurialis or even noma ensued.§ Vogt, however, speaks favorably of the use of calomel both as a purgative, and later in the disease in small repeated doses.‖ Even Niemeyer sanctioned the employment of the latter measure in severe cases of dysentery and in those which resist milder measures,¶ and Heubner refers to it without censure, although he gives greater prominence to the purgative use of the drug.**

In the United States the use of calomel, both in purgative doses and in small doses frequently repeated, found general favor in the treatment of dysentery from an early period in the present century. These measures were advocated by Thacher, Hosack, Eberle, Chapman, Dunglison, Dickson and G. B. Wood.†† At the commencement of the civil war

* AUG. GOTTLIEB RICHTER—*Med. u. chir. Bemerkungen*, Bd. I, Gottingen, 1793, S. 97: "Ich versichre; kein Purgirmittel wirkte so kräftig und zugleich so gelinde, als das Calomel." For the combination of calomel, opium and ipecacuanha mentioned in the text, consult *Die spec. Therapie nach den hinterlassenen Papieren des verstorbenen D. Aug. Gottl. Richter*, &c., herausgegeben von D. GEORG. AUG. RICHTER, 3te Aufl., Bd. II, Berlin, 1821, Abth. 2, S. 134.

† KREYSSIG—*Dysenteria*, Encyclopädisches Wörterbuch der med. Wiss., Bd. IX, Berlin, 1833, S. 657 *et seq.*—commended purgative doses of calomel, especially in inflammatory and bilious dysentery. HAUFF—S. 403, *op. cit.*, p. 534, *supra*—commends it in combination with rhubarb, especially in the gastric and bilious forms. RÖSCH—*Geschichte des Vorkommens der Ruhr in dem Bezirke des Verfassers in den Jahren* 1834 *bis* 1837, *mit ausführlicher Schilderung der Epidemie von* 1837 *und ihrer Behandlung*, Medicinische Annalen, Bd. V, 1839. S. 443—gave half-scruple or even scruple doses, which he repeated, if necessary, twice, three times or even oftener, during the Schwenningen epidemic of 1837. A. SIEBERT—*Zur Genesis und Therapeutik der rothen Ruhr*, &c., Bamberg, 1839, S. 155—gave two to three grains of calomel every two hours, repeated until the often-described green stools made their appearance. He did not aim to produce ptyalism, but did not regard its occurrence as a serious matter, S. 147. BERNDT—*Klin. Mittheil.*, Hefte 3, u. 4, Greifswald, 1840, S. 224—wrote: "Ja, die Behandlung mit grossen Gaben von Calomel wirkt so sicher, dass man in 36–48 Stunden Herr des ganzen Krankheitszustandes werden kann." SCHWEICH—*Ruhr*, Encyklopädie der Gesammten Med., Bd. V, Leipsic, 1842, S. 329—regarded calomel in large doses as a direct antiphlogistic, and declared that its use has found no decided opposers. C. CANSTATT—*Spec. Path. u. Ther.*, 3te Aufl., (Henoch.) Bd. I, Erlangen, 1854, S. 523—gave the preference to scruple or half-scruple doses, once or twice daily, and remarks: "Auch wir halten nach eigener Erfahrung dieses Mittel für eines der wichtigsten und haben beobachtet, dass dasselbe, richtig angewendet, oft rasch die Intensität der Krankheit bricht und ihren Verlauf mildert und abkürzt."

¶ NIEMEYER—Bd. II. S. 756, *op. cit.*, p. 645, *supra*: "Man gibt gewöhnlich 2 stündlich gr. j Kalomel mit gr. ¼ Opium, und ich glaube, dass diese Form, zumal wenn man ausserdem Abends 5–10 Gr. Pulv. Doweri reicht, den Vorzug vor den gleichfalls empfohlenen grossen Dosen Kalomel (3ss) verdient."

** HEUBNER—S. 545, *op. cit.*, p. 529, *supra*.

†† JAMES THACHER—*American Modern Practice*, Boston, 1817, p. 589—not only sometimes used calomel as a cathartic, but remarked: "During the intervals of the operation of the cathartics, small doses of calomel and opium, as directed in fevers, will be productive of excellent effects, by opening the secretions, deterging the intestines, and abating distressing pain." DAVID HOSACK—*Lectures on the Theory and Practice of Physic*, edited by his friend and former pupil, H. W. DUCACHET, Philadelphia, 1838. p. 364—preferred the saline cathartics to calomel in purgative doses, but expressed the opinion that the latter "is doubtless a valuable medicine in this disease," and "especially when administered as a sudorific, in combination with small doses of antimony, or James' powder or with ipecacuanha." JOHN EBERLE—*A Treatise on the Practice of Medicine*, 5th Ed., Philadelphia, 1841, Vol. I, p. 240—commended the administration of 10 to 12 grains of calomel as a purgative early in dysentery. He says: "Calomel should always form a part of our laxative remedies in this disease, particularly in its early stage;" and that "Calomel, with a view to its constitutional influence, is a remedy of excellent powers in this disease." As a diaphoretic he commends the following: "℞.—Pulv. ipecac. compos. gr. xxiv. Submuriatis hydrarg. gr. vi.—M. Divide

they were at the height of their popularity. The clinical observations of Austin Flint had, indeed, a few years before, proved "adverse to the opinion of any favorable influence being exerted by this remedy on the morbid processes involved in the disease;" but he himself had admitted that the number of his observations was "insufficient to settle positively this practical question;" and his cautious criticism of the popular practice does not appear to have borne much fruit.* Even in the essay of Stillé, distributed to the medical officers of our armies by the Sanitary Commission at an early period of the war, although the author cautions against the dangers of the "primary depressing influence" of the drug, and the possibility of its occasioning salivation or "the other and remoter effects of mercurial poisoning," and declares it to be the duty of the army surgeon not to employ mercury, whether in large or in small doses, unless simpler remedies prove inefficacious,† there are several passages in which he commends the administration of calomel under particular circumstances, both in purgative and in small repeated doses.‡

Accordingly it is not remarkable that calomel figured largely in the treatment of dysentery both in the field and in general hospitals, as is shown by the official reports§ and articles published in the American medical journals,‖ and as all who had an opportunity for observation at the time will well remember. It was also freely used in other diseases by many American physicians, especially in pneumonia and the phlegmasiæ generally. A great sensation was therefore created, both in the army and among practitioners in civil life, by the Circular of Surgeon General Hammond, issued May 4, 1863, which, after reciting that the reports of medical inspectors and the sanitary reports received at his office showed that the administration of calomel was so frequently pushed to excess by the

into six equal parts. S. Give one every three or four hours," p. 242. CHAPMAN, in his lectures—*A Compendium of Lectures on the Theory and Practice of Medicine, delivered by Professor Chapman, in the University of Pennsylvania. Prepared with permission, from Dr. Chapman's manuscripts, and published with his approbation*, by N. D. BENEDICT, Philadelphia, 1846, p. 133—commended mercurial purges in the early stages of the dysenteries of warm weather, and later in the disease directed "opium in combination with calomel and ipecacuanha." ROBLEY DUNGLISON—*The Practice of Medicine*, 3d Ed., Phila., 1848, Vol. I, p. 113—remarks that, "in those cases, that are accompanied by signs of great prostration, * * * the strength may have to be supported, whilst every effort is made to induce a new action in the system by means of mercurials." S. H. DICKSON—*Elements of Medicine*, Phila., 1855, p. 524—not only gave calomel in acute dysentery, but says of the treatment of chronic dysentery—p. 531—"I would advise a mercurial course, combining small doses of calomel or of blue mass, with cret. pp. or Dover's powder, repeating at proper intervals throughout the day, and administering full doses of anodyne at night." G. B. WOOD—Vol. I, p. 573, 1st Edit., cited p. 691, *supra;* "Not only is calomel useful in the commencement as a purgative, but afterwards also, in smaller doses, so as to stimulate the hepatic secretory function, and sustain a flow of bile into the bowels. * * * Two grains of opium, from two to four of ipecacuanha, and from two to four of calomel, may be made into four pills, two of which may be given at once, and one every hour or two afterwards till rest is procured. * * * If the disease should not begin to yield in six or seven days, the mercurial may be more freely administered, so as to affect the mouth. * * * No remedial influence is more effectual in dysentery than that of mercury." In chronic dysentery he favored the use of blue pill, remarking: "Pushed to moderate salivation, it will undoubtedly often effect cures; and this measure should always be resorted to if others fail," p. 580. These teachings are repeated without modification in the sixth edition of his work, Phila., 1866, Vol. I, p. 721 *et seq.*

* AUSTIN FLINT—p. 210, *op. cit.*, p. 710, *supra.*

† STILLÉ—p. 370, *op. cit.*, p. 658, *supra.*

‡ *E. g.*, its use as a purge is commended in mild dysentery (10 to 20 grains followed by castor oil) on p. 361; in bilious dysentery (20 grains of ipecacuanha with 10 or 15 of calomel as an emeto-cathartic) on p. 370. On p. 365, speaking of inflammatory dysentery, he writes: "If the patient is not of a vigorous constitution and is not affected with purely sthenic dysentery, purgative doses of calomel are preferable to the salines. These should be prescribed in the dose of twenty grains, with a grain of opium in a single dose, or in two or three doses of from five to ten grains of calomel, and one grain of opium in each, to be taken at intervals of six or eight hours, and followed, after a similar space of time, by an ounce of castor oil." In the same connection, after directing for the subsequent treatment, "Five-grain doses of Dover's powder every five or six hours, or from three to five grains of ipecacuanha, with half a grain or a grain of opium at like intervals;" he adds: "If the sthenic character of the symptoms be still decided, a grain of calomel may be added to each dose of either of the powders just referred to. But such an addition is not generally advisable, owing to the risk of inducing salivation."

§ Thus, among the reports in Section II, purgative doses of calomel or blue mass, or "mercurial cathartics," alone or in combination, are commended by VAN SLYCK—p. 66, *supra;* BRADLEY—p. 67, *supra;* MARTIN—p. 73, *supra;* BRETZ and MULFORD—p. 80, *supra;* BROWN—p. 81, *supra;* STRONG—p. 84, *supra;* SANBORN and HUNT—p. 94, *supra;* and COFFMAN—p. 97, *supra.* The alterative use of calomel, hydrargyrum cum creta, blue pill, or "mercurials," is commended by SCHÜSSLER—p. 44, *supra;* BENJ. WOODWARD—p. 51, *supra;* SCHELL—p. 70, *supra;* LEE—p. 71, *supra;* FOYE—p. 73, *supra;* BROWN—p. 77, *supra;* WHITE—p. 85, *supra;* GRANGER and PECK—p. 86, *supra;* PYLE—p. 91, *supra;* and GAGE—p. 93, *supra.* I suppose the same drug to be indicated by the euphemistic term "alteratives," commended by some of the reporters, *e. g.:* YORK—p. 88, *supra;* MILLER—p. 89, *supra;* and BATES—p. 99, *supra.*

‖ See, for example, Surgeon J. F. HAMMOND, U. S. A.—p. 69, *op. cit.*, p. 697, *supra;* Surgeon J. H. THOMPSON, 12th Maine vols.—*Letter to Editor*, Boston Med. and Surg. Jour., Vol. LXVI, 1862, p. 338; T. H. WALKER—*op. cit.*, p. 708, *supra;* A. D. COSBY—p. 154, *op. cit.*, p. 626, *supra*—who strongly commends scruple doses of calomel, and claims to have successfully treated in this manner a large number of cases of dysentery in the 17th Kentucky volunteers a month before the battle of Shiloh. In the fall of 1862 he used the same treatment in the 35th Kentucky mounted infantry: "I served with the regiment six months, and can now truthfully say that not a man died, not one was discharged from service, or sent to general hospital on account of diarrhœa, during that time, as my monthly reports will show." See also, Asst. Surgeon GEO. WINCH, 29th Wisconsin vols.—*Camp diarrhœa near Vicksburg*, Chicago Med. Jour., Vol. VI, 1863, p. 346; and J. R. BLACK—*op. cit.*, p. 708, *supra.*

military surgeons as to call for prompt measures to correct the abuse, directed that it be struck from the supply table of the army, and that no further requisitions for this medicine should be approved by Medical Directors.*

Although the promulgation of this circular was defended in several articles, which appeared in contemporary medical journals,† it was fiercely attacked and violently denounced in others.‡ A few weeks after it appeared the medical profession of the city of Cincinnati held a meeting, at which several physicians, who had made more or less extensive observations in the western armies and general hospitals, utterly denied the existence of the alleged abuses; a passionate report was adopted, which strikingly indicates the prevailing indignation.§ The American Medical Association met in Chicago, June 2d. A committee of one from each state was appointed to consider the Surgeon General's circular; they made a temperate and carefully considered but firm report, expressing their belief "that the charge of wholesale malpractice made by the Surgeon General is unjust to the army surgeons;" presented, in support of this belief, the testimony of a number of prominent physicians who had had opportunities for observation in both the eastern and the western armies, and

---

* The following is the text of this circular:

"(Circular No. 6.) SURGEON GENERAL'S OFFICE, *Washington, D. C., May* 4, 1863.

"I. From the reports of Medical Inspectors and the Sanitary reports to this office, it appears that the administration of calomel has so frequently been pushed to excess by military surgeons as to call for prompt steps by this office to correct this abuse; an abuse the melancholy effects of which, as officially reported, have exhibited themselves not only in innumerable cases of profuse salivation, but in the not infrequent occurrence of mercurial gangrene. It seeming impossible in any other manner to properly restrict the use of this powerful agent, it is directed that it be struck from the Supply Table, and that no further requisitions for this medicine be approved by Medical Directors. This is done with the more confidence as modern pathology has proved the impropriety of the use of mercury in very many of those diseases in which it was formerly unfailingly administered.

"II. The records of this office having conclusively proved that diseases prevalent in the Army may be treated as efficiently without tartar emetic as therewith, and the fact of its remaining upon the Supply Table being a tacit invitation to its use, tartar emetic is also struck from the Supply Table of the Army. No doubt can exist that more harm has resulted from the misuse of both these agents, in the treatment of disease, than benefit from their proper administration. W. A. HAMMOND, *Surgeon General.*"

It has been already shown—note §, p. 690, *supra*—that so far as this order relates to tartar emetic it was not without precedent. The reader will be interested to learn that a similar order with regard to calomel was contemplated in the year 1841 by military medical authority in India: J. MACPHERSON—p. 548, *op. cit.*, p. 714, *supra*—after expressing the opinion that calomel has been much abused in the treatment of dysentery in India, writes: "Indeed, it has been stated, that the present distinguished Inspector General proposes to issue an order, forbidding the use of calomel among the Queen's troops." I find no record that this proposed order was actually issued. On the other hand, if we may believe TROUSSEAU—*loc. cit.*, note *, p. 716, *supra*—a military order compelling all surgeons in the English service to use large doses of calomel in the treatment of dysentery was actually issued in 1812 in consequence of the success of this method in the hands of AMIEL at Gibraltar. I have been unable to corroborate this statement by any English authority.

† I note the following articles as more or less distinctly taking a favorable view of the circular: EDITORIAL—*Calomel and tartar emetic in the army*, Amer. Med. Times, Vol. VI, 1863, p. 297; Surgeon C. C. COX, U. S. vols.—*Remarks before the Amer. Med. Ass. on the order of the Surgeon General*, same Vol., p. 299; EDITORIAL—*Calomel and tartar emetic as remedial agents*, same Jour., Vol. VII, 1863, p. 8; "ILLINOIS"—*Calomel and tartar emetic in the army*, same Vol., p. 103; "AN INTELLIGENT ASSISTANT SURGEON OF A REGIMENT IN THE FIELD"—*Calomel and tartar emetic*, The Med. and Surg. Reporter, Vol. X, 1863, p. 275; EDITORIAL—*Calomel and tartar emetic as remedial agents*, Buffalo Med. and Surg. Jour., Vol. III, 1863, p. 32; J. F. HIBBERD—*Circular No. 6 and the profession*, The Cincinnati Lancet and Observer, Vol. VI, 1863, p. 429; and by the same—*Circular No. 6 again*, same Vol., p. 483; EDITORIALS—*The Surgeon General's order; calomel and antimony*, The Chicago Med. Jour., Vol. VI, 1863, p. 285, and *Calomel in the army*, same Vol., p. 310; EDITORIAL—*Surgeon General Hammond's anti-calomel and antimony order*, The San Francisco Med. Press. Vol. IV, 1863, p. 116. I may add that on examining the letter files of the Surgeon General's Office for 1863, I find letters expressing approval of the circular from Surgeon L. J. DIXON, 1st Wisconsin vols., May 31; Asst. Surgeon J. H. SHOOT, 4th Mo. state militia cavalry, June 1; Dr. J. W. HITCHCOCK, late surgeon 18th Indiana vols., June 9; Surg. E. BENTLEY, U. S. vols., June 30; Prof. J. A. ALLEN, Rush Medical College, July 7; Dr. WM. SWEETSER, New York, July 10; Dr. E. INGALS, Chicago, July 11; Surg. P. A. JEWETT and nine members of the surgical staff of the Knight Hospital, New Haven, July 14; Prof. J. KNIGHT, Yale College, July 15; also a letter from Surg. G. W. RAMSAY, 95th New York vols., expressing agreeable surprise at the order, and hoping that iodide of mercury may be issued instead of calomel, and one from Dr. GEO. H. GAY, of Boston, received October 13, 1863, in which the writer expresses an opinion "adverse to a routine use in the army, of either calomel or tartar emetic."

‡ I note on this side the following articles: E. P. BENNETT—*Removal of calomel and tartar emetic from the supply list*, Amer. Med. Times, Vol. VI, 1863, p. 298; Z. PITCHER—*Calomel and tartar emetic in the army*, same Jour., Vol. VII, 1863, p. 53; see also Med. and Surg. Reporter, Vol. X, 1863, p. 213; C. G. C.—*Circular No. 6*, same Vol., p. 139; EDITORIAL—*Calomel and tartar emetic*, Med. and Surg. Reporter, Vol. X, 1863, p. 77; EDITORIAL—*Surgeon General Hammond*, Ohio Med. and Surg. Jour., Vol. XV, 1863, p. 448; EDITORIALS—*Circular No. 6*, The Cincinnati Lancet and Observer, Vol. VI, 1863, p. 369; *Surgeon General Hammond's circular No. 6*, same Vol., p. 440; *Circular No. 6 once more*, same Vol., p. 497; *The Surgeon General in a new order*, same Vol., p. 553; Surg. J. R. BLACK, 113th Ohio vols.—*Letter*, in same Vol., p. 424; EDITORIAL—*Calomel and tartar emetic as remedial agents*, The Chicago Med. Examiner, Vol. IV, 1863, p. 342; "A SURGEON"—*Calomel in the army*, Chicago Med. Jour., Vol. VI, 1863, p. 254; EDITORIAL—*Calomel and tartar emetic stricken from the supply table of the army*, Pacific Med. and Surg. Jour., Vol. VI, 1863, p. 237. I find also on the files of the Surgeon General's Office for 1863 a lengthy communication by Surgeon WM. LOMAX, 12th Indiana vols., dated June, 1863, in which the circular is severely criticised, and a letter, dated June 7, 1863, to the Secretary of War, from Governor DAVID TOD, of Ohio, who transmits "one of the many letters" he had received on the subject from Ohio physicians, and expresses the opinion that the Surgeon General's order "will prove most disastrous to the medical service, and should at once be revoked."

§ At this meeting, which was held May 30, 1863, Dr. L. M. LAWSON presided. Among the physicians who testified in the manner related in the text were Drs. D. C. MUSCROFT, G. C. BLACKMAN, MENDENHALL, JUDKINS, COMEGYS and SEXTON. An abstract of the proceedings and the text of the report will be found in the Cincinnati Med. and Surg. News, Vol. IV, 1863, p. 217. The report embraced the following forcible resolution: "Resolved, that the removal of W. A. Hammond from his position as Surgeon General would meet the approbation of the profession, be of advantage to our soldiers and creditable to the Government."

offered for the consideration of the association a series of resolutions in which the circular was condemned as "unwise and unnecessary," and the Surgeon General was requested to modify it. These resolutions were unanimously adopted.*.

A few days after the announcement of this action Surgeon General Hammond sent out a printed letter requesting the opinions of "the more eminent members of the medical profession" on the subject, pointing out that various other mercurials were still on the supply table, and intimating that calomel itself could be obtained upon special requisition. A copy of this letter and an analysis of the replies on file in the Surgeon General's Office are subjoined in a foot note.† I also subjoin a foot note containing all the evidence I have

* See *Trans. of the Amer. Med. Ass.*, Vol. XIV, 1864, p. 23 *et seq.* The subject was introduced to the notice of the association by Dr. LAWSON of Ohio, who presided over the Cincinnati meeting, and he was appointed chairman of the committee. The other members were STILES of Vermont, DALTON of Massachusetts, CATLIN of Connecticut, BRINSMADE of New York, PIERSON of New Jersey, ASKEW of Delaware, WALLACE of Pennsylvania, HUPP of Virginia, WOODWORTH of Indiana, WING of Illinois, PALMER of Michigan, VAN DUZEN of Wisconsin, MCGUGIN of Iowa, MENDENHALL of Missouri, LOGAN of Kansas and BOWLING of Tennessee. The following are the resolutions adopted: "*Resolved*, 1. That this Association condemns, as unwise and unnecessary, the Circular of the Surgeon General, prohibiting the further supply of calomel and tartar emetic for use in the army, and that we regard such an order as an indignity to the military surgeons, while it is in direct opposition to the opinions of the regular profession of medicine. *Resolved*, 2. That the withholding ordinary medicines from the Army Surgeons implies a want of confidence in their skill as a body, which, if true, calls for the prompt interposition of the proper authorities; but if the imputation of a want of skill is unfounded, as we believe it is, the refusal to supply proper medicines is wholly unjustifiable. *Resolved*, 3. That Circular No. 6, being impolitic and prejudicial to the interests of the service, it is the decided sense of this Association, that a due regard for the welfare of the army requires, and we do therefore earnestly recommend, the revision of that circular and the substitution of the more just and philosophical method of correcting abuses, if any exist, by holding each surgeon individually responsible for the proper discharge of his appropriate duties." Of course certain irregular practitioners were jubilant over the order: I find on the letter files of the Surgeon General's Office for 1863 a letter, dated June 10, signed by PAUL W. ALLEN, president, and C. EDWIN MILES, recording secretary, of the Massachusetts Eclectic Medical Society, transmitting resolutions passed at the annual meeting of that society, June 3, 1863, in which the circular is warmly commended, and the society tenders its "heartfelt congratulations to Surgeon General Hammond for the liberal and independent position which he has assumed in this matter."

† The following is the text of this letter:

"SURGEON GENERAL'S OFFICE, *Washington City, D. C., June* 12, 1863.

"DEAR SIR: Desiring to obtain the opinions of the more eminent members of the Medical Profession relative to the indiscriminate use of Calomel and Tartarized Antimony, I have the honor to request that you will answer the following questions: 1st. To what extent do you prescribe Calomel and Tartar emetic in your practice? 2d. Do you regard these agents as indispensable in the treatment of disease? 3d. In view of the facts that a large number of the Medical Officers of the Army are young and inexperienced, and that soldiers cannot in the field be placed beyond the influence of atmospheric vicissitudes and exposure whilst undergoing medical treatment, would you recommend that the medicines in question be issued to Army Medical Officers, except, as at present, upon special requisition? 4th. Do you or do you not think that more harm than good has resulted from the use of Calomel and Tartar emetic as medicines? It should be stated that the following mercurials are at present on the Supply Table, viz: Hydrargyri chloridum corrosivum; hydrargyri iodidum flavum: hydrargyri oxidum rubrum; hydrargyri pilulæ; hydrargyri unguentum; hydrargyri nitratis unguentum; pilulæ catharticæ compositæ; and that it is provided by paragraph 13, of Circular No. 7, dated Surgeon General's Office, May 7, 1863, which contains the Supply Table, and which refers to the manner of obtaining medical supplies, that 'it is not the design of the Department to confine Medical Officers absolutely to that table, either in variety or quantity, but only to establish a standard for their guidance in making requisitions for supplies, leaving individual preferences to be indulged at the discretion of the Medical Director or the Surgeon General. Neither is it supposed that the quantities of the table will always meet the necessities of unusual emergencies, as during epidemics, or in unhealthy seasons and localities; and Medical Officers who allow their supplies to be exhausted through any such contingencies, without timely notice of their approaching necessities, will be held to a strict accountability.'

I am, sir, very respectfully, your obedient servant,

WILLIAM A. HAMMOND, *Surgeon General U. S. A.*

To Doctor —— ——."

This letter was reprinted in the American Medical Times, July 4, 1863, Vol. VII, p. 8. I find sixty replies on the files of the Surgeon General's Office, only two of them from civil practitioners. The following is a list of the writers:

1. Surg. J. F. HAMMOND, U. S. A., June 29;
2. Surg. WM. DICKINSON, U. S. V., July 1;
3. Asst. Surg. J. C. MCKEE, U. S. A., July 3;
4. Surg. S. D. FREEMAN, U. S. V., July 4;
5. Surg. J. H. BAXTER, U. S. V., July 4;
6. Surg. W. S. KING, U. S. A., July 6;
7. Surg. E. BENTLEY, U. S. V., July 6;
8. Surg. J. WILSON, U. S. V., July 8;
9. Asst. Surg. W. F. CORNICK, U. S. A., July 8;
10. Surg. H. CULBERTSON, U. S. V., July 9;
11. Surg. O. A. JUDSON, U. S. V., July 10;
12. Dr. J. J. REESE, Philadelphia, July 10;
13. Surg. W. H. WHITE, U. S. V., July 10;
14. Surg. J. G. HATCHITT, U. S. V., July 10;
15. Surg. A. CRISPELL, U. S. V., July 10;
16. Surg. C. S. TRIPLER, U. S. A., July 10;
17. Surg. J. J. B. WRIGHT, U. S. A., July 11;
18. Asst. Surg. J. TRENOR, U. S. V., July 11;
19. Surg. B. B. WILSON, U. S. V., July 12;
20. Surg. H. BUCKMASTER, U. S. V., July 12;
21. Surg. B. CLOAK, U. S. V., July 13;
22. Surg. J. H. GROVE, U. S. V., July 14;
23. Surg. S. D. TURNEY, U. S. V., July 15;
24. Surg. J. MOSES, U. S. V., July 16;
25. Surg. B. RANDALL, U. S. A., July 16;
26. Surg. G. R. WEEKS, U. S. V., July 17;
27. Surg. J. M. ROBINSON, U. S. V., July 17;
28. Dr. JOHN MCCALL, Utica, N. Y., July 18;
29. Surg. H. P. STEARNS, U. S. V., July 18;
30. Surg. J. D. BRUMLEY, U. S. V., July 18;
31. Surg. W. VARIAN, U. S. V., July 19;
32. Surg. J. G. F. HOLSTON, U. S. V., July 22;
33. Surg. S. N. SHERMAN, U. S. V., July 22;
34. Surg. D. W. BLISS, U. S. V., July 24;
35. Surg. J. W. FOYE, U. S. V., July 24;
36. Surg. T. M. GETTY, U. S. A., July 25;
37. Surg. W. HAYES, U. S. V., July 25;
38. Surg. H. WARDNER, U. S. V., July 25;
39. Surg. O. M. BRYAN, U. S. V., July 27;
40. Surg. A. L. COX, U. S. V., July 27;
41. Surg. P. A. O'CONNELL, U. S. V., July 27;
42. Surg. F. G. SNELLING, U. S. V., July 31;
43. Surg. J. OWEN, U. S. V., July 31;
44. Surg. J. E. QUIDOR, U. S. V., Aug. 1;
45. Surg. A. MAJER, U. S. V., Aug. 7;
46. Surg. T. W. FRY, U. S. V., Aug. 8;
47. Surg. A. R. EGBERT, U. S. V., Aug. 10;
48. Surg. R. K. SMITH, U. S. V., Aug. 11;
49. Surg. G. H. HUBBARD, U. S. V., Aug. 15;
50. Surg. C. N. CHAMBERLAIN, U. S. V., Aug. 16;
51. Surg. J. S. HILDRETH, U. S. V., Aug. 17;
52. Asst. Surg. B. HOWARD, U. S. A., Aug. 18;
53. Asst. Surg. C. WAGNER, U. S. A., Aug. 20;
54. Surg. C. C. DUMREICHER, U. S. V., Aug. 22;
55. Surg. M. GOLDSMITH, U. S. V., Aug. 23;
56. Surg. A. P. MEYLERT, U. S. V., Aug. 28;
57. Surg. J. R. LUDLOW, U. S. V., Oct. 29;
58. Med. Insp. PETER PINEO, U. S. A., July 14;
59. Med. Insp. F. H. HAMILTON, U. S. A., July 12;
60. Med. Insp. GEO. H. LYMAN, U. S. A., June 27.

In reply to the first question in the Surgeon General's letter, two writers only, Nos. 20 and 53, declared that they never employ either drug; and two, Nos. 7 and 8, stated that they did not employ either in military practice. On the other hand, six, viz: Nos. 9, 16, 17, 18, 19 and 24, boldly avowed and defended the use of both drugs in appropriate cases; thirteen, viz: Nos. 4, 5, 13, 14, 15, 29, 31, 32, 35, 38, 41, 47 and 52, approved of calomel in appropriate cases, but claimed to use it rarely and with great caution, while they either did not use tartar emetic, used it externally only, or passed it by in silence. The remaining writers, thirty-seven in number, admitted that they sometimes used both remedies, but either indicated a few conditions only, *e. g.*, yellow fever, syphilis, &c.,

been able to collect with regard to the abuse of calomel in the army prior to the issue of the circular of May 4th.*

This circular was never modified or revoked in orders, but it was suffered to become a dead letter, and I find no evidence that it exercised any perceptible effect upon the use of

---

as appropriate, or stated that they have rarely used these drugs of late years, or have rarely done so in the military service. In reply to the second question, six writers, viz: Nos. 9, 16, 18, 21, 24 and 36, declared that they regarded both drugs as indispensable; nine, viz: Nos. 3, 12, 13, 38, 42, 47, 54, 57 and 60, while they did not hold them to be indispensable, thought that they are more useful than any other drugs under particular conditions; six, viz: Nos. 14, 19, 29, 31, 32 and 46, expressed a similar view for calomel only; and one, No. 2, for tartar emetic only; the remaining writers, thirty-eight in number, stated that in their opinion neither drug is indispensable. In reply to the third question, thirteen writers, viz: Nos. 1, 9, 12, 16, 17, 18, 19, 24, 31, 32, 45, 51 and 54, objected more or less decidedly to the limitations imposed; four, viz: Nos. 15, 20, 28 and 34, thought it would be just as well if neither drug was issued to the army at all; two, Nos. 21 and 59, expressed no opinion; while the remainder, forty-one in number, believed it would answer every purpose if these drugs could be obtained on "special requisition." In reply to the fourth question, four writers only, Nos. 1, 16, 17 and 21, boldly declared their belief that these drugs have done more good than harm; ten, viz: Nos. 2, 12, 14, 18, 19, 24, 36, 46, 47 and 60, contented themselves with denying the truth of the opposite proposition; ten, viz: Nos. 10, 11, 13, 15, 22, 26, 35, 39, 43 and 44, thought them calculated to do more harm than good in the army; two, viz: Nos. 55 and 56, thought they had done more harm than good in the southwest of the United States; seven, viz: Nos. 3, 20, 30, 32, 37, 42 and 54, spoke in a general way of the injury resulting from their indiscriminate or injudicious use; fifteen, viz: Nos. 4, 5, 7, 8, 23, 25, 27, 28, 33, 41, 48, 49, 52, 53 and 58, flatly expressed the opinion that they have done more harm than good; one, No. 31, expressed the same opinion for tartar emetic only; the remaining writers, eleven in number, gave non-committal replies.

* This evidence certainly shows that mercurials were abused in certain quarters, but there is by no means so much of it as seems to be implied by the unlucky circular of May 4th. There are in the first place two pretty strongly worded reports on the official files, one by a medical inspector, one a sanitary report, both of which, so far as they relate to this matter, are printed in full in Section II. The first is by Medical Inspector E. P. VOLLUM, dated April 23, 1863—see p. 94, *supra*—who reports that the surgeons in charge of the hospital transports and floating hospitals "complain of the number of cases of salivation" sent them from the regimental hospitals; and adds that he himself "saw two cases of mortification of the cheek from mercurialization. In both, one side of the head was greatly swollen, and a circular black surface about three inches in diameter occupied the central part of the cheek. Copious discharges of the foul secretions from the mouth rendered approach to the patients sickening." The second is a "sanitary report," by Surgeon A. H. HOFF, U. S. Vols., (afterwards assistant surgeon U. S. Army,) dated September 30, 1862—see p. 91, *supra*. Surgeon HOFF was in charge of the hospital steamer D. A. January, and states that most of the men placed on that boat for transportation "have been subjected to treatment and show evidences of its effects." Speaking of the cases of "intermittent and remittent fever complicated with diarrhœa," transported in the last two trips of the boat, he affirms "very many of these men, as high as fifty per cent., are salivated, yet the fever still persists." These two reporters were both competent observers and gentlemen of undoubted integrity, so that there can be no doubt that the facts they report actually existed at the times and places stated. Surgeon HOFF was one of the surgeons alluded to in Medical Inspector VOLLUM'S report, for, in reply to an inquiry of the Surgeon General, the latter wrote, June 11, 1863: "As I reported before, I saw on board the hospital boats of the Mississippi two cases of mortification of the cheek produced by mercurialization, said to have come from regimental hospitals, and Surgeon Hoff in charge of the 'D. A. January,' and Surgeon Strawbridge, in charge of the 'Vicksburg,' complained to me of the number of cases of salivation that came from the same source." In addition to the two cases of mercurial gangrene observed by Medical Inspector VOLLUM, a third case, terminating in the separation, by necrosis, of the whole right superior maxillary bone, had previously been reported to the Surgeon General's Office, where the specimen was sent, for the Army Medical Museum, some time before the close of 1862. [It appears in the Catalogue of the Army Medical Museum, Surgeon General's Office, January 1, 1863. p. 31, as "No. 557. Right superior maxillary bone, separated spontaneously; gangrene of face following salivation."] The name of this patient, private Carlton Bergan, Co. B, Purnell Legion, appears on the register of the general hospital at Frederick, Maryland, as "admitted July 4, 1862;" diagnosis, "typhoid pneumonia." The case-book of this hospital, kept under the direction of Assistant Surgeon R. F. WEIR, U. S. Army, surgeon in charge, reports that this man, 20 years of age, was "taken sick June 5, 1862, from exposure to wet, and suffered from cold and rheumatic pains. He continued ill, though not so as to keep his bed all the time till July 4, 1862, when he was sent to hospital (one of the detached buildings in Frederick) sick with typhoid fever. Aug. 3 was brought to this general hospital sick with fever." A special report of the case, received at the Surgeon General's Office, states that he was "admitted general hospital, Frederick, Md., August 4, 1862;" and this is the date given in the printed reports of the case, to which I shall presently refer. To understand this apparent discrepancy in the date of admission, it must be stated that at the period named the general hospital at Frederick embraced, besides the principal hospital in the old stone barracks, four temporary hospitals in detached private buildings scattered through the town. All were, however, under a single administration, and accordingly when Bergan was taken, as Dr. WEIR states, to one of these detached buildings, his name was entered on the register of the general hospital. What the case-book and special report give as the date of his transfer to "this general hospital," Aug. 3d or 4th, was simply the date at which he was transferred from the detached building to the old stone barracks. The case-book cited above states that the reporter "learned from ——— surgeon, under whose care he was, previous to entering my ward, that he had salivated him but not profusely, a fortnight before his removal, for a tenderness in right side. He had subsequently administered chlorate of potass for six days;" also that "It has been ascertained that the quantity of mercury the patient took before entering this hospital [*i. e.*, this ward of the hospital.—Ed.] was 65 grs. of pil. hydrarg., 40 grs. of hydrarg. chlor. mit., and 20 grs. hydrarg. c. creta." Acting Assistant Surgeon J. H. BARTHOLF (now Assist. Surg., U. S. A.) states, in the special report referred to above, that "prior to admission at this hospital [*i. e.*, this ward.—Ed.] patient had taken for treatment of pneumonia a large quantity of mercury. As afterwards ascertained he took 65 grs. pil. hydrarg., 40 grs. hydrarg. chlor. mit., and 20 grs. hydrarg. c. creta." I have taken the trouble to present the foregoing evidence that this dosing occurred in a detached ward under the same administrative control as the rest of the general hospital at Frederick, because this circumstance made it possible for Drs. WEIR and BARTHOLF to ascertain with precision just what this man did take, and there can be therefore no doubt that their statements are accurate. The details of the progress of the case after August 4th, the separation of the necrosed maxillary bone, October 1st, the discharge of the patient from the service, December 23d, and the subsequent successful plastic operations performed upon him in the New York hospital by Dr. GURDON BUCK have been related in full by that gentleman—*Trans. of the Med. Soc. of the State of New York for the year* 1864, p. 173—and by my colleague, Assistant Surgeon G. A. OTIS, in the First Surgical Volume of this Work, p. 375; it is therefore unnecessary to do more in this place than refer to them. The foregoing constitutes all the testimony with regard to the occurrence in the army of salivation or mercurial gangrene received at the Surgeon General's Office prior to May 4, 1863, which I have been able to find. The following testimony, for the most part referring to the same period, was received subsequently: Surgeon J. H. GROVE, U. S. Vols., in charge of the Jefferson barracks, general hospital, St. Louis, Missouri, writes, July 14, 1863, in his reply to the Surgeon General's circular letter of June 12: "During last fall and winter I received quite a large number of patients into this hospital who were ptyalised, and for which there evidently was no necessity, their diseases generally being chronic diarrhœa and some cases of phthisis pulmonalis." Medical Inspector PETER PINEO, U. S. A., in his reply to the same circular, writes, from New Orleans, July 14, 1863: "During more than two years experience in active service I have seen much harm arising from the indiscriminate use of these articles, [*i. e.*, calomel and tartar emetic.] less, however, in this Department [*i. e.*, the Department of the Gulf.—Ed.] than in others where I have been;" and he adds: "In examining the prescriptions of the surgeons in the different hospitals here, I find as a general rule very little of either of these two medicines ordered. Mass. hydrargyri is more commonly prescribed, and that not continuously but occasionally as a cholagogue cathartic." Finally I find a report by Acting Assistant Surgeon S. W. THOMPSON, in charge of hospital No. 2, Evansville, Indiana, to Surgeon WM. H. CHURCH, U. S. Vols., Medical Director, Department of the Ohio, and forwarded by the latter to the Surgeon General, July 15, 1863. In this report, which is dated July 9, it is stated that "Private Ptolemy Hughes of Co. A, 91 Regt. Ind. Vols., was admitted into this hospital July 7, 1863, laboring under severe ulceration of the gums, the result of the administration of

mercurials, whether in the fluxes or other diseases, during the war.* So far as the fluxes are concerned, many medical officers treated them with purgative doses of calomel or blue pill, or employed alterative doses of these or mercury with chalk, until the close of the war; and although many avoided mercurials altogether, or at least avoided them in the chronic fluxes, this was true also before the issue of the circular as well as afterwards.† I know of no method of ascertaining the extent to which either mode of practice prevailed, or of determining statistically their comparative results.

Conversation with American practitioners inclines me to believe that the influence of the English example has, during the last few years, greatly diminished the use of these drugs in the treatment of fluxes in the United States; yet it must be admitted that calomel is still commended in the "sthenic" type of acute dysentery by at least one prominent American teacher.‡ For myself, I have long since ceased to employ any preparation of mercury in the treatment of any form of flux, and my study of the literature of the subject inclines me to believe that no advantages are to be expected from them that can counterbalance the serious objections to their use, especially in military practice. Their employment would be theoretically justifiable only, if it were true, as has been so often asserted, that they increase the diminished hepatic secretion, or that they modify favorably the condition of the intestinal mucous membrane. So far as the first assumption is concerned, it has already been shown in sufficient detail that it is positively contradicted by experiment.§ As to the second suggestion, it is known that calomel undergoes, under different circumstances, various chemical decompositions in the alimentary canal,‖ some of

mercurials. This man had had erysipelas very badly, and to render his condition worse than it otherwise would have been, the severe ptyalism to which I refer existed. This is not an isolated case in this regiment. Just before the receipt of your circular I had two companies of this regiment under my charge, as acting assistant surgeon. There were at least a dozen cases of severe ptyalism amongst them, all being contracted at Smithland, Kty., in hospital under charge of the regimental medical officers. This I obtained from both privates as well as officers of the companies. Some of these cases were very aggravated, there being deep ulcers in the cheeks, tongue, &c., and excessive swelling and inflammation of all the salivary glands." As to the occasional occurrence of salivation in the Cincinnati hospitals, we have the testimony of the report cited in note §, p. 719, *supra*, which states: "The medical profession here have had an opportunity to observe in the military hospitals of this city and vicinity, the condition of about twenty-five thousand cases of sick and wounded soldiers, and a careful examination of the records shows that no more than nine cases of ordinary salivation have existed; and not one case of mercurial gangrene has been seen." This statement may be accepted as conclusive as to the existence in the Cincinnati hospitals of at least nine cases of mercurial salivation. It does not prove that there were no more. Those who are familiar with the manner in which hospital records were kept during the war will know how impossible it would be to ascertain the number of cases of salivation which may have occurred in any hospital during a given period of time by the records; and an examination of the records of the Cincinnati hospitals, now filed in the Surgeon General's Office, shows that they offer no data for such a research. In such an inquiry the recollection of the medical officers on duty would furnish the only information.

* According to the Editor of the Medical and Surgical Reporter, Sept. 12, 1863, Vol. X, p. 275, a "correspondent, holding a high position in one of our grand armies," wrote to that journal: "For my own part, despite the order, I get plenty of calomel, and use it without hesitancy." The statement compiled by Surgeon W. C. SPENCER, U. S. A., (see p. 708, *supra*,) shows that the quantity of calomel actually purchased for the army during the war was 166,016 ounces, avoirdupois, besides 683,131 dozen of the compound cathartic pills of the U. S. Pharmacopœia, each of which contained a grain of calomel. According to information furnished by my colleague, Surgeon J. S. BILLINGS, U. S. A., 25,847 ounces of calomel and 194,684 dozen compound cathartic pills remained unissued in the purveying depots Dec. 31, 1865. The total quantity issued was therefore 140,169 ounces of calomel and 488,447 dozen compound cathartic pills. This quantity is altogether the equivalent by weight of more than three and a half millions of scruple doses of calomel issued. It is, of course, impossible to ascertain how much of this was actually swallowed by the sick, but as so much was available for use, it cannot certainly be held that the supply was at all a meagre one.

† Thus, Surgeon POTTER of the 30th Ohio vols.—p. 83, *supra*—reports March 31, 1862, that in the diarrhœa of that regiment he found mercurials "almost universally injurious." Acting Assistant Surgeon DEBRULER—p. 42, *supra*—writes from hospital No. 2, Evansville, Indiana, August 30, 1862, that in the treatment of chronic fluxes in that hospital "mercurials, opiates and the ordinary astringents have been worse than useless;" and a number of the earlier reporters in Section II, in describing the treatment they found best for camp fluxes, do not even allude to mercurials.

‡ H. C. WOOD—p. 436, *op. cit.*, p. 675, *supra*—declares: "In dysentery of an acute sthenic type, calomel has yielded, in my hands, better results than any other remedy. It probably acts as an antiphlogistic and as an alterative, not only to the liver, but to all the intestinal glands." In this connection I may mention also the paper of J. F. KENNEDY—*On the use of calomel in large doses in the treatment of dysentery and diarrhœa*, Med. and Surg. Reporter, Vol. XXIII, 1870, p. 467—who reports three cases of acute dysentery in adults successfully treated with doses of a scruple or more of calomel at bedtime, and two of acute diarrhœa in children treated with equal success with proportionately large doses. The author naïvely remarks: "The remedy is not a new one, nor the dose;" and a letter from J. S. SUESSEROTT—Philadelphia Med. Times, Vol. VIII, 1878, p. 115—who reports the successful treatment of two cases of chronic flux by a purge of calomel, aloes and rhubarb, followed by laudanum in ten-drop doses every hour.

§ See pp. 275 to 277, *supra*, especially the notes, for an account of the experiments on this subject. Since those pages were printed RUTHERFORD and VIGNAL have published a *Third series* of their *experiments on the biliary secretion of the dog*—The Journal of Anatomy and Physiology, Vol. XI, 1877, p. 654 *et seq.*—in which a further examination of the question only served to confirm their previous conclusion that calomel does not increase the biliary secretion. On the other hand, this effect was produced in a decided manner by small doses of corrosive sublimate—see p. 724, *infra*.

‖ On the subject of the various chemical changes which calomel undergoes under different circumstances, see, especially, R. BELLINI—*Contributo alla storia terapeutica del calomelano o proto-cloruro di mercurio*, Lo Sperimentale, T. XXXI, 1873, p. 634. A brief abstract of the more important conclusions arrived at by this experimenter will be found in STONE'S *Half-yearly Abstract of the Medical Sciences*, Vol. LVIII, 1873, p. 130; also in the monograph of H. HALLOPEAU—*Du Mercure*, Paris, 1878, p. 53 *et seq.*

the products of which are highly irritating to the intestinal mucous membrane, and that it appears to owe its power of purgation to the irritation thus produced.* The same is probably true of the mercury in blue pill, and the oxide it contains when administered is directly irritating. It has not been proven that this intestinal irritation is beneficial in its effects, and the variable character and extent of the chemical changes that occur with a given dose of these purgatives in different individuals render their effect uncertain. A quantity which may be safely taken by some patients will in others produce serious local disturbances: worst of all, unexpected salivation is occasionally produced even after comparatively small doses.† Against these objections no convincing evidence, that the use of mercurial purgatives in the treatment of the fluxes is followed by better results than may be obtained by less dangerous drugs, has as yet been brought forward. On the contrary, we have seen that it is claimed by the English physicians in India that since they have substituted ipecacuanha in the treatment of dysentery the percentage of mortality from that disease has greatly diminished.‡

There are yet graver objections to the administration of repeated small doses of mercurials to dysenterics with a view to their alterative or supposed antiphlogistic effects. Aside from the dangers of salivation and other forms of mercurial poisoning, the debilitating effect of this mode of treatment constitutes a serious objection in morbid conditions in which the tendency to debility is already great; and the fact that an acute intestinal catarrh is one of the most frequent accidents of the constitutional impression of mercury, however produced, would seem to contraindicate the employment of this measure in cases in which the intestinal canal is already inflamed.§ Nothing, then, could justify a resort to the constitutional impression of mercury in the management of the fluxes but the certainty that it exercised a beneficial effect upon the progress of the local morbid process. Loud assertions to this effect have been made, as we have already seen, but the evidence brought forward to support them is anything but conclusive. The numerous instances reported, in which dysenteric patients thus treated have recovered, prove only that many individuals are capable of surviving the treatment as well as the disease. There is no proof whatever that the percentage of recoveries is greater among those mercurialized than among those treated in other ways; indeed, the general tenor of the evidence is in the opposite direction.

These objections to the use of mercurials in the treatment of the fluxes apply to cases occurring in civil life as well as to army practice; but in the latter an additional objection is to be found in the wide-spread tendency to a scorbutic condition which has always arisen in every great army that ever kept the field for any length of time in any war. Since Kramer reported the fatal results of the attempt to cure scurvy by salivation in the camp of the imperial army at Semendria in the year 1718,‖ observations of the disastrous effects of the mercurial impression, when ventured upon in scorbutic subjects, have multiplied,

* See on this subject HALLOPEAU—*op. cit.*, p. 71.

† Even mercurial gangrene has been known to occur after the exhibition of comparatively small purgative doses of calomel. An extreme instance of this accident is reported by A. CAMPBELL—*Fatal effects of calomel*, The India Jour. of Med. Sci., Vol. I, 1834, p. 74. The patient, a boy 14 years old, suffering with malarial fever, took a purgative dose of three grains of calomel and eight of colocynth, followed next morning by a drachm of compound powder of jalap. This operated freely, and was repeated with the same result two days afterwards. Two days later the mouth began to swell, and mercurial fœtor, ulceration and gangrene of the gums, palate and lips followed, from which the patient died fifteen days after the first dose.

‡ See note ¶, p. 698, *supra*. § See HALLOPEAU—*op. cit.*, p. 104.

‖ J. G. H. KRAMER—*Disp. epistolica de scorbuto*, Nuremberg, 1737, in Haller's Disp. ad Morb. Hist. et Cur. fac., T. VI, Lausanne, 1758, p. 135—relates that in 1718 salivation having been resorted to in the treatment of scurvy then prevailing in the imperial camp at Semendria, (in Servia, near Belgrade,) four hundred of the patients thus treated died. An abstract of this dissertation will be found in the treatise of LIND—*On the Scurvy*, 2d Ed., London, 1757, p. 403. R. KREBEL—*Der Scorbut*, Leipsic, 1866, S. 13—states this event occurred in 1720, but KRAMER, writing his *casus medicus Cæsaream militiam attinens* in 1720, says it happened two years before: "Quod etiam fatalis eventus approbavit, ubi Semendriæ dictæ ante biennium 400 scorbutici ex gregariis Cæsareanis in salivatione periere."

and it has long been admitted, even by ardent advocates of the use of mercurials in dysentery, that their employment in this disease is contraindicated by the coexistence of a scorbutic taint.* The same considerations of course apply to diarrhœa, or indeed to any other disorders complicated by scorbutic conditions.

Before leaving the subject of the use of mercurials in the fluxes, I must refer to the suggestion that minute doses of *corrosive sublimate* might advantageously be resorted to for the purpose of obtaining, in the most certain and least dangerous manner, the supposed benefits of the alterative effects of mercury. This method, recommended in 1827 by Kopp, who had previously employed corrosive-sublimate injections in dysentery with apparent advantage,† has since been warmly approved by several writers, especially by Eisenmann.‡ Parkes claimed to have given with advantage as much as one-eighth to one-sixth of a grain at a dose in certain cases of chronic dysentery.§ Quite recently Ringer has revived the method of Kopp, and states that the hundredth of a grain of corrosive sublimate, given every hour or every two hours according to the severity of the case, whether in acute or chronic dysentery provided the stools are slimy or bloody, rarely fails to free them from blood and slime and to relieve the disease.‖ The experiments of Rutherford and Vignal show that corrosive sublimate, in comparatively small doses, increases the hepatic secretion of the dog;¶ and it is exceedingly probable that it acts in the same way on man. It is possible that this property, as well as its alterative effects, may prove beneficial in the treatment of the fluxes, and certainly it offers a convenient mode of giving a mercurial in definite minute doses, and thus avoiding the depressing influence which, as ordinarily administered, mercurials are so apt to exert.** The evidence is, however, as yet insufficient to enable us to arrive at a just estimate of the value of this mode of treatment.

---

* Without attempting to collect the testimony to this effect, I may refer to the experience of ANNESLEY, who found—Vol. II, p. 391, *op. cit.*, p. 621, *supra*—that in scorbutic dysentery "calomel, particularly when given in full doses, readily affects the mouth and salivary apparatus, without being followed by any beneficial effect upon the disease, but, on the contrary, often aggravating it, and increasing the debility of the patient." This experience is corroborated by the observations of PARKES—p. 143, *op. cit.*, p. 682, *supra*. MARTIN—p. 458, *op. cit.*, p. 621, *supra*—goes still further, remarking, "nor should mercury in any shape be used in adynamic forms of the disease, in the splenic cachexia, nor in states of anæmia—for in all these conditions of the system its actions are most injurious."

† J. H. KOPP—*Merkur bei Ruhren und Durchfällen*, Hufeland's Journal, Bd. LXIV, 1827, St. 4, S. 92—used the sublimate in very small doses. He added $\frac{1}{8}$ to $\frac{1}{4}$ of a grain of corrosive sublimate and 12 to 18 drops of Sydenham's laudanum to seven ounces of gum water: dose, a tablespoonful every hour. The corrosive-sublimate clysters are described in his *Beob. im Gebicte der ausübenden Heilkunde*, Frankfort, 1821, S. 128. The formula was $\frac{1}{8}$ to $\frac{1}{2}$ of a grain of sublimate and a grain of opium to two ounces and a half of gum water: a wineglassful (ein Glas voll) to be injected warm. In the subsequent paper, cited above, he remarks that often the quantity of sublimate contained in the clyster should not exceed $\frac{1}{16}$ to $\frac{1}{12}$ of a grain.

‡ EISENMANN—*Die Krankheits-Familie Typhus*, Erlangen, 1835, S. 410—declared that corrosive sublimate was "ein vorzügliches Mittel" in dysentery. He regarded it as a disinfectant, and expressed the hope that it would drive calomel out of therapeutics: "Wir hoffen überhaupt, dass der als ein so intensives Desinfektionsmittel vielfältig erprobte Sublimat, das zweideutige Calomel, das bey den grossen Dosen, in welchen es oft gegeben werden muss, gar zu leicht nachtheilig würkt, aus der Therapie der fieberhaften Krankheiten allmälig verdrängt werde." BAMBERGER—S. 417, *op. cit.*, p. 578, *supra*—in mentioning these suggestions, seems to regard the clysters at least worthy further trial.

§ PARKES—p. 151, *op. cit.*, p. 682, *supra*—recommended this treatment in the form of chronic dysentery "following colonitis or erythematous dysentery." He remarks: "The preparation I have found most useful is the bichloride of mercury, commencing with doses of one-eighth to one-sixth of a grain in combination with the preparations of cinchona. I know that this combination has been called unchemical, but it certainly loses no part of its activity by the changes that occur; nor is there any insoluble salt of mercury formed."

‖ S. RINGER—*A Handbook of Therapeutics*, 4th Ed., Amer. reprint, New York, 1875, p. 223—also commends minute doses of corrosive sublimate in several forms of the diarrhœa of children: "A single grain of bichloride dissolved in half a pint of water, and a teaspoonful of this given each hour," p. 222. I note that R. RAVENBURG—*Acute intestinal catarrh of infants, and its treatment by mercuric chloride, (corrosive sublimate,)* The Medical Record, Vol. XIV, 1878, p. 4—recommends a similar treatment, and explains its alleged efficacy by the supposition that the sublimate acts as a parasiticide, destroying the micro-entozoa imagined by him to cause the disease. He writes: "I prescribe one grain of the mercuric chloride to twelve ounces of distilled water. One teaspoonful to be mixed with an ordinary teacupful of milk, previously subjected to at least 150° F. for five minutes; the milk should never be brought to the boiling point. Of the milk so prepared I give to the infants as much at a time as age and the condition of the patient may demand." C. H. HALL—*Corrosive sublimate in intestinal catarrh*, same Vol., p. 194—has since reported the successful treatment of three cases by this method.

¶ RUTHERFORD and VIGNAL—*loc. cit.*, note §, p. 722, *supra*.

** In this connection I may refer to the essays of WILBOUCHEWITCH—*De l'influence des préparations mercurielles sur la richesse du sang en globules rouges et en globules blancs*, Archives de Physiologie, 2me Série, T. I, 1874, p. 509; and E. L. KEYES—*The effect of small doses of mercury in modifying the number of the red blood corpuscles in syphilis; a study of blood-counting with the hématimètre*, The Amer. Jour. of the Med. Sci., Vol. LXXI, N. S., 1876, p. 17. The patients observed by WILBOUCHEWITCH were syphilities treated in hospital, who took daily 4 centigrammes of corrosive sublimate or 10 centigrammes of the protiodide of mercury. The effect was at first an increase in the number of red blood corpuscles and diminution in that of the white corpuscles, but the long-continued use of these doses produced a diminution in the number of red globules also. KEYES attributes the latter result partly to the depressing effects of hospital life, partly to the dose of mercurial being too large. He himself concludes that "mercury in small doses continued for a short or for a long period in syphilis, alone or with the iodide of potassium, increases the number of red corpuscles in the blood,

It remains to offer a few *concluding remarks on the use of purgatives* in the fluxes. The history of those discussed will serve to indicate the general favor with which remedies of this class have been regarded from the earliest times; but their use in the treatment of dysentery has not been universally accepted. The disapproval of Galen and the caution of Avicenna have already been referred to.* During the sixteenth century several physicians, prominent among whom were L. Fuchsius and Alexander Massaria, strongly protested against them. The latter of these writers clearly formulated the apprehension that they would act as additional irritants to the already inflamed intestinal mucous membrane. These objections, to which Sennertus offered a well considered reply,† had long been forgotten, when they were revived in a slightly modified form by the teachings of Broussais.‡ Such was his influence for a time that when Roche, in 1830, declared both emetics and purgatives to be dangerous in acute colitis, he assured his readers that he was but expressing the opinion of the great majority of the practitioners of the day.§ Yet the success of Bretonneau and Trousseau|| with saline cathartics had already shown that these supposed dangers were greatly exaggerated, and the doctrines of the physiological school gradually lost credit even in France. It may be admitted that a free resort to drastic cathartics would be likely to prove hurtful to the inflamed intestines, and ought to be avoided, a caution which has been repeated by prudent physicians from the earliest times;¶ but the temporary irritation of the intestinal mucous membrane produced by properly selected salines and other mild cathartics is of a trifling character and does not interfere with the benefits resulting from their action.**

---

and maintains a high standard of the same." The observations brought forward to support this conclusion were made upon patients who took daily from three to eight granules containing $\frac{1}{8}$ of a grain of protiodide of mercury, or who took three times a day with various quantities of iodide of potassium, $\frac{1}{24}$ to $\frac{1}{12}$ of a grain of biniodide of mercury, or $\frac{1}{24}$ to $\frac{1}{18}$ of corrosive sublimate. He further concludes that "mercury in small doses is a tonic (for a time at least) to individuals in fair health, not syphilitic. In such individuals, it increases the number of the red blood corpuscles." This conclusion is based upon the results of an experiment upon himself: He took $\frac{1}{8}$ of a grain of protiodide of mercury three times daily for two weeks. At the beginning of the experiment his blood counted 4,775,275 globules per cubic millimetre, at the close 5,562,062 globules.

* See pp. 703-4, *supra*.

† L. FUCHSIUS—*Paradoxorum Medicinæ Libri tres*, &c., Basel, 1535, Lib. II. Cap. 13, fol. 81. In this chapter, which is headed "Omnium exitiosissimum esse, veterumque placitis maxime adversum, dysenteria affectos purgantibus exacrnificari medicamentis," the author supports his views by texts from GALEN, ALEXANDER OF TRALLES, CELSUS and AVICENNA. He argued especially, and in this was doubtless correct, that the rhubarb of DIOSCORIDES and other ancient writers was the astringent and not the purgative variety. According to SENNERTUS—*loc. cit.*, *infra*—FUCHSIUS maintained similar views in his treatise *De Comp. Med.*, Lib. I, Cap. 84, which I have not been able to see; nor have I been able to examine for myself the opinions of ALEXANDER MASSARIA, of whose works we have only, in our library, his treatise *De Peste*, Venice, 1579. SENNERTUS states—*loc. cit.*—that he objected at great length to the use of purgatives in dysentery, relying especially on the doctrine of GALEN, that in treating disease the peccant humor should not be attracted to the affected part nor evacuated through it. He reasoned, says SENNERTUS, as follows: "Cum ergo in dysenteria intestina cum fluxione, tum ulcere, sæpe etiam inflammatione laborent, non licere putat, purgantia exhibere, quæ fluentes humores ad illa magis attrahant, doloremque ulceris et alia symptomata augeant." SENNERTUS—*Quæstio IV*, cited note *, p. 705, *supra*—in reply endeavored to show that these objectors misunderstood the teachings of the ancients, pointed out that even GALEN, in common with other Greek physicians, used abstergents in dysentery, among other articles, for example, milk, and argued, in reply to the objections of MASSARIA, that it was better for the patient the physician should evacuate the vicious humors from the intestines at once, in a few copious stools, than leave them to the efforts of nature, which will usually require many protracted and painful efforts to effect the same end: for during this delay the morbid juices will surely exert a more injurious influence upon the intestines than properly selected purgatives could possibly do.

‡ BROUSSAIS—T. III, p. 268 *et seq.*, *op. cit.*, p. 643, *supra*—tanght that two indications sufficed for the treatment of dysentery: "1°. d'épargner à la membrane phlogosée la présence des corps étrangers qui pourraient augmenter son irritation; 2°. de lui faire parvenir ceux qui jouissent d'une propriété opposée." It might be thought that purgatives would play a prominent role under the first of these indications, but this is not so. The author insists on abstinence from stimulating drinks and food that can leave an excrementitial residue in the intestines, appearing to regard the bowels as quite able in most cases to disembarrass themselves of any noxious matters they may contain at the beginning of the disease, without the assistance of art. Only when there is depression of the vital powers does he advise emetics or purgatives, "afin de solliciter les fibres musculaires des voies gastriques, qui sont déjà dans la stupeur, à se débarrasser des matières putrides provenant, soit des alimens, soit des excrétions bilieuses, muqueuses, etc." p. 211. But even this limited use of purgatives appears to have been neglected by his followers. A. FOUQUET—*De la Dysenterie*, Vannes, 1852, p. 16—writes: "L'école physiologique repousse les purgatifs du traitement de la dysenterie, parce que ce sont des agents constamment irritants et perturbateurs." The views of ROCHE—cited next note—may be taken as a fair representation of the opinions of that school on this matter.

§ L. CH. ROCHE—Art. *Colite*, Dict. de Méd. et de Chir. Pratiques, T. V, Paris, 1830, p. 354—advised that neither emetics nor purgatives should ever be used in dysentery: "Quoi qu'il en soit, il est bien démontré aujourd'hui, ce me semble, que les vomitifs et les purgatifs sont en général plus nuisibles qu'utiles dans la colite aiguë, et que, faute de signes propres à nous faire distinguer à l'avance les cas dans lesquels ils peuvent nuire de ceux dans lesquels ils peuvent produire de bons effets, le parti le plus sage est de s'en abstenir dans le traitement de cette maladie. On serait d'autant plus coupable d'en agir autrement, qu'il est toujours possible de les remplacer par des moyens plus certains et qui ne font pas courir les mêmes chances aux malades."

|| See p. 707, *supra*. ¶ See p. 704, *supra*.

** In a former publication—WOODWARD, p. 228, *op. cit.*, p. 606, *supra*—I expressed the opinion that when in acute dysentery "the bowels are once thoroughly cleansed, purgatives are no longer admissible; they do not modify favorably the progress of the disease, and increase the prostration which usually exists" I have long since abandoned this view, as I have the preference for castor oil, expressed in the same paragraph.

In the present state of our knowledge, purgatives may reasonably be administered to patients laboring under the fluxes, with three distinct objects: (a) To evacuate noxious matters contained in the alimentary canal; (b) to increase or modify the secretion of the intestinal mucous membrane; and (c) to increase the biliary secretion in acholic conditions. (a) With regard to the first of these indications there can be no material difference of opinion. All the fluxes are characterized by disturbances of the digestive functions, in consequence of which more or less decidedly fermentative or even putrefactive processes go on in the intestinal contents. Not merely are the products of these changes a source of irritation at the commencement of acute attacks, when a good deal of undigested food is often contained in the alimentary canal, but during the subsequent stages of the disease, although the quantity of the intestinal contents is usually smaller, the abnormal character of the chemical changes is often more marked and their products more irritating, especially when ammoniacal compounds are set free. Any efficient purgative that is not itself capable of producing serious intestinal disturbance would answer to evacuate these abnormal products, and were this the only indication to be fulfilled, the taste of the patient and the mildness yet thoroughness of the action of the drug would be all that need be considered in making a choice.

(b) As to the possibility of fulfilling the second indication some difference of opinion has of late arisen. The experiments of Thiry, repeated by Schiff and Radziejewski, together with the more elaborate investigations of the latter,* seemed to show that the general belief in an increase of the intestinal secretion resulting from the action of purgatives was quite unfounded, and that their powers were limited to a mere increase of the peristaltic motions of the intestines. But the subsequent investigations of Moreau indicated that these researches cannot be regarded as conclusive, and that sulphate of magnesia at least actually does increase the intestinal secretion. Moreau's experiments were repeated with similar results by Vulpian and Lauder Brunton;† the former also obtained like effects with resin of jalap,

* L. THIRY—*Über eine neue Methode den Dünndarm zu isoliren*, Sitzungsberichte der Mathematisch-Naturwiss. Classe der kais. Akad. der Wiss., Bd. L, 1864, S. 19—performed his experiments as follows: He divided the ileum or jejunum of dogs in two places, and sewed together the divided extremities of the intestine so as to restore the continuity of the canal. One end of the isolated piece, which still remained attached to the mesentery, was sewed up, the other end was attached to the edges of the abdominal wound, where it remained open, forming a short *cul-de-sac*. If the animal did not speedily die of inflammation, it usually began to eat again on the third or fourth day, and by the fourteenth the wounds were sufficiently healed to permit it to be used for experiment. Now THIRY found that when he purged a dog, thus prepared, by senna or sulphate of magnesia introduced into the stomach, or by croton oil rubbed upon the skin of the belly, no increase took place in the secretion of the *cul-de-sac;* nor was this effect produced when the two former drugs were introduced directly into the *cul-de-sac*. These experiments on dogs were repeated by SCHIFF—*Nuove ricerche sul potere digerente del succo enterico*, Il Morgagni, anno nono, 1867, p. 642—who introduced into his *cul-de-sacs*, in preparing which he took pains to make as little torsion as possible on the mesenteric vessels of the isolated part, aloes, jalap, sulphate of soda and calomel, and obtained either very slight increase of secretion or none at all. Similar were the results obtained by S. RADZIEJEWSKI—*Zur physiologischen Wirkung der Abführmittel*, Reichert u. Du Bois-Reymond's Archiv, Jahrg., 1870, S. 37—who repeated THIRY's experiment on a young bitch with croton oil and sulphate of magnesia. Moreover he analyzed chemically the normal fæces of dogs fed on flesh, and those produced by various purgatives, and concludes that nothing is found in the latter that cannot readily be explained on the theory of increased peristalsis, without invoking increased transudation or secretion to account for any of the ingredients. He proved by experiment that several purgative substances actually do increase the peristaltic motion of the intestine, and endeavored to show that the fluid stools cannot be explained by the observation of A. MOREAU—*De l'influence de la section des nerfs sur la production de liquides intestinaux*, Comptes Rendus, T. LXVI, 1868, p. 554—that the section of the nerves going to a loop of intestine is followed by an increased secretion from the mucous membrane.

† A. MOREAU—*Expériences sur l'intestin*, (read before the Acad. de Méd., July 5, 1870,) Gazette Méd. de Paris, T. XXV, 1870, p. 374—combated the conclusions of THIRY and RADZIEJEWSKI by experiments, in which he held that he more nearly approximated the normal conditions. Two ligatures were applied to the small intestine of a dog, 15 to 20 centimetres apart. Into the space between these ligatures he injected 20 cubic centimetres of water containing 4 grammes of sulphate of magnesia in solution. The intestine was then returned to the abdomen, the wound closed and the animal left in repose. This operation was performed on eight dogs, which were killed at various intervals from six to twenty-four hours afterwards, and in every instance a considerable accumulation of fluid, 50 to 335 cubic centimetres, was found between the ligatures. He also modified the experiment of THIRY by ligating both ends of the isolated loop of intestine and injecting into it immediately after the operation the same quantity of solution of sulphate of magnesia mentioned above, and found next day that the loop contained 90 cubic centimetres of liquid. In a subsequent paper—*Expériences sur l'intestin*, (suite,) read before the Acad. de Méd., Sept. 12, 1871, same Jour., T. XXVI, p. 415—MOREAU reports a still further investigation of THIRY'S mode of experimentation, from which he is led to suggest several explanations of the negative results obtained by him and RADZIEJEWSKI: Either, 1, the purgatives introduced into the loop do not remain there long enough to produce their characteristic action, for which some time is required; or, 2, after recovery from the operation the interior extremity of the *cul-de-sac* is not closed and the fluid injected escapes into the peritoneal cavity; or, 3, the intestinal mucous membrane in the *cul-de-sac* may, in some cases after the operation, submit in its abnormal position to atrophic changes which render it incapable of responding to stimuli that would readily act on the normal mucous membrane. VULPIAN—Comptes Rendus, &c., de la Soc. de Biologie, Sér. V, T. V, 1874, p. 182, séance du 17 Mai, 1873—repeated the experiments of MOREAU in a modified manner on dogs poisoned with curara or morphia. He concludes that sulphate

the latter with croton oil, elaterin and gamboge. Yet more recently Brieger,* at the suggestion of Cohnheim, performed a series of experiments very similar to those of Lauder Brunton, but with a still greater number of substances. From these he concluded that laxatives, such as senna, rhubarb, castor oil and aloes, do not augment the intestinal secretion, and that their action must be explained by increased activity in the peristaltic movements; that the neutral salts certainly possess the power of producing a discharge of watery fluid from the intestinal mucous membrane mingled with increased secretion; and that drastics, such as croton oil and colocynth, when given in sufficient doses, not only produce a similar effect, but that the secretion is mingled with inflammatory products. It seems, therefore, to be pretty well established by experiment that the neutral salts produce a greater increase in the intestinal secretions, with less local irritation, than can be obtained with any other purgatives with which we are acquainted.

Vulpian has gone so far as to conclude, from the dissection of dogs to whom purgative doses of sulphate of magnesia and resin of jalap had been given, that these drugs occasion a genuine intestinal catarrh; and if this name is to be bestowed upon every condition in which there is increased vascularity of the intestinal mucous membrane accompanied by increased secretion, this conclusion must probably be regarded as correct. Certainly the suggestion of Liebig, that the saline cathartics occasion watery stools by merely determining free osmosis from the bloodvessels into the intestinal canal, a view which has long been rejected by thoughtful therapeutists, appears now more than ever untenable.† But many additional investigations will be required before we shall be in a position to determine with

of magnesia produces a genuine intestinal catarrh with increased transudation and without material increase in the activity of the peristaltic action. On the other hand, resin of jalap dissolved in dilute alcohol, while it produced a more intense catarrh, (not merely vascular congestion, but veritable ecchymosis being observed,) exaggerated the peristaltic movements. In discussing this paper LEGROS stated that he also, in connection with ONIMUS, had satisfied himself by experiment a few years before that saline purgatives do not increase the activity of the peristaltic movements. T. LAUDER BRUNTON—*On the action of purgative medicines*, The Practitioner, Vol. XII, 1874, p. 345 *et seq.*—experimented on cats by opening the abdomen, tying four ligatures around the small intestine a few inches apart from each other so as to isolate three short portions of the intestine; the purgative medicine is then injected into the central portion by means of a hypodermic syringe, the intestine returned to the abdomen and the wound sewed up. A few hours after, the animal being killed, the portion into which the purgative was injected was found full of liquid, while the two adjoining portions, ligated in the same manner, remained empty. This result was obtained with the purgatives mentioned in the text. A similar experiment with jalapin produced negative results, but the author reports that he is uncertain in this case whether a sufficient quantity was actually introduced. I note in these experiments that, while croton oil inflamed the mucous membrane with which it was brought in contact, this was not the case with sulphate of magnesia, "not the slightest trace of congestion was noticeable."

* L. BRIEGER—*Zur physiologischen Wirkung der Abführmittel*, Archiv für Exp. Pathologie und Pharmakologie, Bd. VIII, 1878, S. 355—injected the purgative substances into the first and last loops of intestine, and left the central loop empty for comparison, but otherwise followed the method of BRUNTON; see last note. Five grammes of a half-per-cent. solution of sulphate of magnesia injected into the first loop, and the same quantity of a one-per-cent. solution injected into the last, were wholly reabsorbed without producing other effect. After injection of the same quantity of a twenty-per-cent. solution the loops were always distended with a clear yellowish fluid, which possessed the power of transforming starch into grape sugar and of dissolving raw fibrin. Similar effects were produced by 4 grammes of a fifty-per-cent. solution, as well as by a saturated solution of Glauber's salt, and, though to a much less degree, with a saturated solution of common salt. The drastics experimented with were croton oil dissolved in ether or olive oil, and extract of colocynth dissolved in water; in these experiments the mucous membrane of the loop was inflamed, and many red and white blood corpuscles, as well as flocculi of fibrin, were found with the microscope, which was not the case with the salines. When such laxatives as infusion of senna, powdered rhubarb, aloes or its extract and castor oil were introduced, the intestinal loop was always found empty, firmly contracted, its mucous membrane not inflamed to the slightest degree, and the substance introduced was found still present, spread out over the mucous membrane of the loop. These experiments appear to have been made with great care, and the dogs were killed at various intervals, 4½, 5, 7 and 16 hours, after the introduction of the laxatives mentioned, but always with the same result. I must, therefore, confess some surprise at finding that BRIEGER reports similar results, to those obtained with the laxatives named, with calomel and gamboge, (gummi gutti,) both of which he classes as laxatives. The first, indeed, was given in a small dose, 25 centigrammes to a dog, so that the question of the action of a larger dose remains open; but it seems strange that the quantities of gamboge used, 2 and 3 grammes of a ten-per-cent. solution, produced no greater effect.

† This suggestion of LIEBIG, first thrown out in his *Unters. der Mineralquellen zu Soden und Bemerkungen über die Wirkung der Salze auf den Organismus*, Wiesbaden, 1839, S. 4 *et seq.*, is still more clearly formulated in his essay *Ueber die Constitution des Harns der Menschen und der fleischfressenden Thiere*, Annalen der Chemie und Pharmacie, Bd. L, 1844, S. 179, and his *Unters. über einige Ursachen der Säftebewegung im thierischen Organismus*, Braunschweig, 1848, S. 56. Against this view H. AUBERT—*Exper.—Unters. über die Frage, ob die Mittelsalze auf endosmotischem Wege abführen?* Zeitsch. für rat. Med., Jahrg., 1852, S. 225—brought forward a series of experiments which show—S. 239—that a given purgative dose of sulphate of magnesia, or other purging salt, produces the same effect whether dissolved in 6, in 72, or in 100 ounces of water, whereas, if LIEBIG's view were correct, the degree of concentration would be all-important. He suggested, therefore, an action on the intestinal nerves in explanation of the purgative effect produced. Shortly after, H. WAGNER—*Diss. de effectu natri sulphurici*, Dorpat, 1853—working under the direction of R. BUCHHEIM, who has republished the chief results obtained in an essay—*Ueber die Wirkung des Glaubersalzes*, Archiv für Phys. Heilkunde, Jahrg. 13, 1854, S. 93—arrived at results which seemed to show that solutions of the neutral salts, in virtue of their small capacity for diffusion, are very slowly absorbed from the alimentary canal; the foreign mass stimulates increased peristaltic movements and is speedily expelled as a watery stool. The experiments of MOREAU, VULPIAN, LAUDER BRUNTON and BRIEGER, cited above, show that this explanation also is insufficient, and that a physiological transudation (increased secretion) is probably produced by the purgative action of these salts.

certainty the degree of increased secretion and of catarrhal irritation attending the operation of the various cathartics. Meanwhile the practitioner can judge to some extent of the former by the quantity and quality of the stools produced, and of the latter by the gripings and other clinical phenomena which accompany the purgative action.

It may reasonably be expected that, especially in the early stages of a catarrhal inflammation of the intestinal mucous membrane, such as occurs in acute catarrhal diarrhœa and dysentery and in the catarrhal stage of diphtheritic dysentery, the action of purgatives which decidedly increase the intestinal secretion will relieve the congestion of the intestinal bloodvessels, and that, after the temporary increase of vascularity produced by their action has subsided, an improvement in the condition of the mucous membrane will follow. Whether the same benefits can be anticipated in chronic conditions is more doubtful; but even here moderate catharsis, occasionally induced; often proves beneficial, if only by washing out the abnormal contents of the alimentary canal. Lastly, the hope that, either in acute or chronic cases, the intestinal secretions can be beneficially modified by cathartics, except so far as it may be beneficial to increase their quantity and render them more watery, remains at present unsupported by experimental evidence.

(c) More satisfactory, though far from being all that could be desired, is the experimental evidence with regard to the third indication. The observations of Rutherford and Vignal especially show pretty conclusively that there are a number of cathartics which increase the biliary secretion. Some of these, on account of the intensity of the local irritation they produce, are ill-adapted for use in dysentery or the chronic fluxes; but others are medicaments whose mild and unirritating operation is well known, and which, as we have seen, have long been freely used in the treatment of these complaints. Among the neutral salts, sulphate of soda, phosphate of soda and Rochelle salt belong to this category. Rhubarb, long so celebrated in the treatment of dysentery, is also a decided cholagogue.* These are the cathartics upon which, in the present state of our knowledge, we ought to rely in the treatment of fluxes complicated with deficient hepatic secretion, instead of invoking the doubtful properties of calomel.

Diaphoretics.—The Greek physicians early observed the intimate connection between the functions of the skin and the bowels, as is shown by a striking passage in the writings of Hippocrates;† and diaphoresis was one of the modes of evacuating abnormal humors from the body enumerated by Galen;‡ yet I have found no distinct directions in any of

* Rutherford and Vignal—*op. cit.*, p. 722, *supra*—found no evidence of the possession of any cholagogue virtues by castor oil, gamboge or sulphate of magnesia; taraxacum and scammony acted very feebly upon the hepatic secretion; as to the action of croton oil, they were doubtful. Besides the substances mentioned in the text, their experiments indicate the possession of active cholagogue powers by colocynth, colchicum, podophylline, aloes and jalap, the purgative operation of all of which was shown by dissection to produce considerable increased vascularity and other signs of intestinal irritation. Senna, which was much less objectionable in this respect, proved to be a very feeble cholagogue. Sulphate of potassa, an active cholagogue, as well as sulphate of magnesia, produced marked increase of intestinal vascularity, which was less decidedly or less uniformly the case with the purgatives mentioned in the text. Of special interest to the American practitioner are the experiments of these authors with Euonymin, Sanguinarin, Iridin and Leptandrin. The first three of these substances were pretty active stimulants of the hepatic secretion, but they produced also marked indications of intestinal irritation, so that whatever field of usefulness may hereafter be found for these drugs, they will probably not come into successful use in the treatment of the fluxes. Leptandrin, which was less objectionable in this respect, proved to possess but feeble cholagogue virtues.

† Hippocrates—*De Morb. Vulgar.*, Lib. VI, Sect. 3, [Ed. Littré, V, 293:] "Relaxation of the skin, constriction of the belly." Van Swieten—§ 722, T. II, p. 394, *op. cit.*, p. 663, *supra*—has cited this passage in support of the use of diaphoretics in the treatment of the fluxes; and the commentary of Galen—*Comm. III in Epidem. VI*, § 1, [Ed. Kühn, XVII, B, pp. 1-7,]—seems to indicate that a similar application had been made before his time, though he himself did not approve of it. There are, it may be added, two other passages in the Hippocratic writings in which, under certain circumstances, the occurrence of sweating is said to be injurious to patients laboring under the fluxes, viz: in *Prænotiones Coacæ*, Sect. VII, § 628, [Ed. Littré, V, 731:] "In protracted bowel complaints, with vomitings, biliousness, and aversion to food, much sweating accompanied with adynamia kills suddenly." Also, in the same treatise, § 638, [same Vol., 733:] "Chilliness with sweating following upon liquid stools is bad."

‡ In his commentary upon the Hippocratic direction that superfluous humors should be expelled from the body—*De Morb. Vulgar.*, Lib. VI, Sect. 2, [Ed. Littré, V, 277,]—Galen explains—*Comm. II in Epidem. VI*, § 2, [Ed. Kühn, XVII, A, 898,]—that this may be done by emetics, purgatives or clysters, through the urine, by sweating, &c.: "Quod videliect nonnunquam redundantes humores sensibiliter evacuare convenit aut vomitionibus aut clysteribus aut purgatoriis medicinis aut per lotia aut per sudores aut per venæ scissionem aut per ani sanguifluas vocatas venas aut per uterum aut scarificando."

the Greek or Roman writings for the employment of this measure in the treatment of the fluxes.* It is, however, formally commended in the Canon of Avicenna,† and subsequent authors long continued to repeat the precept without, however, appearing to attach very great importance to it. During the sixteenth and seventeenth centuries several of the systematic writers on dysentery, who give, indeed, a more prominent place to other evacuants, refer also to the benefits of diaphoresis as an auxiliary measure; yet for the most part aimed to produce it only by covering the patient warmly in bed and by the use of external heat, obtained by hot bricks under the bedclothes, the hot bath and hot fumigations. These measures figure in the works of Hollerius and Felix Plater, while Hildanus, Sennertus and Riverius commemorate also the sudorific and alexipharmic virtues of the long-renowned but quite inert Bezoar stone.‡

Many of the iatro-chemists, however, paid greater attention to the use of diaphoretics in dysentery, holding that the blood poison they believed to cause the disease could be more thoroughly and promptly expelled in this way than by purgation.§ They invented a variety of distilled waters, each prepared from numerous ingredients, and some of which long enjoyed popular favor in the treatment of dysentery, being supposed to act not merely as diaphoretics but also as antidotes. Among these were the famous *aqua theriacalis*|| and

* This was certainly not because diaphoretics were unknown to them, for it is easy to show, *e. g.*, by ÆTIUS—*Tetrab. I, Serm.* 3, *Cap.* 157, p. 176, Ed. cited p. 656, *supra*—that there were a number of substances which the Greeks believed to possess the power of provoking sweating if given internally, *e. g.*, cumin, bay berries, anise, artemisia, cardamom, castor, &c., with wine or hydromel, as well as certain stimulating liniments and fumigations. CELSUS—Lib. II, Cap. 17, Vol. I, p. 120, Ed. cited p. 656, *supra*—treats at length of the production of sweating either by dry heat or the hot bath, and gives directions for the use of these measures in the treatment of fevers, but says nothing of their applicability to fluxes; in the treatment of which they were, however, frequently employed by the physicians of subsequent ages.

† I have already cited this passage from the *Canon* of AVICENNA—note §, p. 689, *supra*. A comparison of it with the citation from GALEN in note ‡, last page, will show that AVICENNA merely applied the general direction of GALEN to the particular case of the alvine fluxes.

‡ Thus HOLLERIUS—Lib. I, Cap. 40, fol. 122, *op. cit.*, p. 680, *supra*—writes: "Sudor excitatus plurimum prodest viribus valentibus, balneo aut suffumigio ex rebus sudores moventibus. Later calfactus et vino albo conspersus, involutus pannis adhibetur plantis pedum." In a marginal note he adds: "Aut etiam vasculum aqua fervente plenum, nisi resolutionis hepaticæ metus aliquis immineat." Similar are the teachings of FELIX PLATER—T. III, p. 811, *op. cit.*, p. 680, *supra*—who adds that these measures are especially useful if nature already tends toward perspiration, (maxime si natura eo vergat.) FAB. HILDANUS—Cap. 9, p. 684, *op. cit.*, p. 644, *supra*—approved of keeping the patients under warm bedclothes, that those malignant humors contained in the superficial veins might exhale, which exposure to cold might drive inward upon the viscera, but did not favor the use of diaphoretics (sudorifica) as a mode of evacuation, at least in the early stages of the disease. Nevertheless he relates that PHILIBERTUS, a celebrated Saracen physician of Lyons, had found in the Bezoar stone a happy remedy for epidemic dysentery, and had cured a great personage, who seemed about to die, by forty grains of it; half an hour after taking it the patient broke out into a warm sweat, soon fell asleep, and speedily recovered. HILDANUS declared that he had satisfied himself by experience that this is a most excellent remedy for dysentery, if the genuine article be used, and emphasizes the frequency of sophistications. SENNERTUS—*loc. cit.*, *infra*—quotes this story approvingly. Indeed the Bezoar stone enjoyed for a long time considerable reputation in the treatment of dysentery, being supposed to be not merely a valuable sudorific, but an alexipharmic by which the malignity of the disease could be combated. These views are confidently laid down by SAMUEL DALE—*Pharmacologia*, 3d Ed., London, 1737, p. 402—who writes "sudores ciet, alexipharmacus est," and enumerates dysentery, plague and malignant fevers among the many diseases in which, in his time, it was supposed to be useful. The genuine Bezoar orientale was a concretion found in the stomach of the so-called Bezoar goat or gazelle, an animal living in Persia and the East Indies, (probably the antilopus cervicapra;) and there can be now no doubt that the virtues attributed to it were entirely imaginary. Similar concretions from other animals were used, as the B. germanicum, from the chamois; B. occidentale, from the llama of Peru; and the B. hystricum, from the porcupine. The last was even more extravagantly prized than B. orientale, but the others much less so: see DALE—*op. cit.*, *passim*. SENNERTUS—p. 174, *op. cit.*, p. 645, *supra*—thought sudorifics especially useful to those on whom they act easily, and in malignant dysentery. RIVERIUS—Lib. X, Cap. 6, p. 305, *op. cit.*, p. 680, *supra*—writes that medicines prepared from Bezoar (bezoardica) and sudorifics are of great benefit, especially in malignant and epidemic dysenteries. Among the sudorifics he commends the famous *aqua theriacalis*, concerning which see note ||, *infra*.

§ Thus DOLÆUS—*Encycl. Med. Dogm.*, Lib. III, Cap. 5, Opera, Frankfort, 1703, T. I, p. 238—writes: "Chemici egregia possident medicamenta, hoc in morbo probatissima, methodum seq. observantes, ab initio scilicet non purgantibus, sed diaphoreticis eum aggrediuntur, putant enim in dysenteria semper aliquid venenati subesse, potum ergo pestilentialem parant, aquam theriacalem propinant, post expulsionem veneni, confortativum et constrictivum exhibent."

|| Their imperfect knowledge of the properties of bodies led the mediæval chemists to use many substances in the preparation of their distilled waters which were not volatile and could communicate no virtues to the product of the still. Nothing illustrates this better than the fact that distilled waters prepared from the flesh of pullets, capons and the like were long believed to represent in a concentrated form the nutriment of the meat. It would be a thankless task to give an abstract of the literature of this subject, but I may refer to the formulæ for the preparation of *aqua caponis*, *aqua pullorum*, &c., detailed by VALERIUS CORDUS—*Pharmacorum omnium, quæ in usu potiss. sunt, componendorum ratio, Vulgo vocant Dispensatorium sive Antidotarium*, Nuremberg, 1535; I cite the edition of 1592, emended and enlarged by the Nuremberg College of Medicine, pp. 166–7; JOSEPHUS QUERCETANUS—*Pharmacopœa dogmat. restituta*, &c., [1603,] Frankfort, 1607, p. 32. (This work does not describe the preparation I have mentioned in note †, p. 669, *supra*, which I believe is to be found in the *Diæteticon Polyhistoricum* of the same author, Sect. III, Cap. 9, which I have not been able to see;) and VIDUS VIDIUS—*De Medicamentis*, Lib. VII, Cap. 5, Opera, Frankfort, 1626, T. III, p. 222. SENNERTUS—*Institutionum Med.*, Lib. V, Pars 3, Sect. 3, Cap. V, Opera, Paris, 1641, T. I, p. 792—gravely combated the notion that these products were nutritive, declaring: "In eo autem nobis hallucinari, et errare ac non magnæ chymiæ peritiam prodere videntur." But error is hard to eradicate, and I find a formula for a distilled *aqua caponis* in the *Pharmacopœia Collegii Regalis*, London, 1677, p. 35; and several, including that of QUERCETANUS, are given by NICOLAS LEMERY—*Pharmacopée Universelle*, (1697:) I cite 3d Ed., Amsterdam, 1717, pp. 546–7—who still held them to be restorative and fortifying in the dose of two drachms to four ounces, although he admitted that the most nutritive part of the flesh remained in the still, and that a good bouillon would be better food. It may be added that the erroneous belief that these inert distillates were highly nutritious was exploded by the progress of chemistry, rather than by the acuteness of clinical experience

various antipestilential waters, such as the English *aqua epidemica.** At first these products consisted simply of distilled water flavored with the volatile oils of some of the drugs used; for all the more active ingredients were left behind in the still, a circumstance which did not hinder them from long enjoying the blind confidence of physicians. The later pharmacists, however, put into the still a good deal of wine or brandy, so that the resulting preparations contained much alcohol, which probably conferred upon them greater activity than all the other drugs employed.

Meanwhile the diaphoretic virtues of opium and antimony began to attract notice. Sylvius, who pointed out that all the preparations of opium produce perspiration, a doctrine which still survives,† employed the diaphoretic antimony of Basil Valentine in the

which had reposed blind confidence in them for two hundred years. Equally instructive is the lesson as to the danger of trusting to the every day bedside experience of the ordinary practitioner, unchecked by scientific observation and experiment, which is taught by the story of the two famous preparations referred to in the text. The *aqua theriacalis*, or treacle water of the English dispensatories, was a distilled water prepared in a great variety of ways, in accordance with the fancy of different chemists. This precious product derived its name from the circumstance that one of the substances put into the still was the long-renowned antidote or alexipharmic, Theriaca. This was a variously compounded mixture of many ingredients, among which figured always the pastilli theriaci, or lozenges prepared by boiling down the flesh of vipers and rubbing it up with bread. GALEN has discussed the earlier history of this subject at great length in *Ad Pisonem de Theriaca Liber.* [Ed. Kühn, XIV, 210.] and *De Theriaca ad Pamphilianum*, [same Vol., 295,] as well as in his treatise *De Antidotis*, [same Vol., 1.] How the subject still appeared to many minds as late as the beginning of the seventeenth century may be seen by the elaborate discussion of QUERCETANUS—Lib. I, Cap. 23, *De Theriacis*, p. 169 *et seq.*, *op. cit.*, *supra*. The theriaca, commonly employed in the preparation of the distilled water, was professedly modelled upon the theriaca of ANDROMACHUS the elder, who added the pastilles of vipers, and otherwise modified the famous antidote of MITHRIDATES. GALEN tells the story in the treatise cited above, and gives the formula in *De Antidotis*, Lib. I, Cap. 6, [Vol. cited, p. 32.] Having been repeated by PAULUS ÆGINETA—Lib. VII, Cap. 11, Vol. III, p. 511, *op. cit.*, p. 624, *supra*—the English reader can conveniently compare the ingredients as given in the excellent translation of Dr. ADAMS with those of "The treacle of Andromachus, Venice treacle," described by WILLIAM SALMON—*The New London Dispensatory*, Lib. IV, Cap. 22, 3d Ed., London, 1685, p. 660—and JOHN QUINCY—*The Dispensatory of the Royal College of Physicians in London*, 2d Ed., 1727, p. 103; or compare the formula recorded by GALEN with that headed Theriaca Andromachi in the London Pharmacopœia of 1677, p. 102, cited *supra*. Both in its older and more modern forms the nostrum contained over sixty ingredients, several of them compounds. Besides the viper pastilles, to which superstitious importance was attached, it contained opium, squill and a great variety of astringents, aromatics, &c. It is stated in the *Edinburgh New Dispensatory*, 2d Ed., 1789, p. 585 *et seq.*, that theriaca and Mithridatum had then been for some time abandoned in the Pharmacopœias of both London and Edinburgh Colleges. The former substituted the confectio opiata, which, in a somewhat simplified form, still survives as the confection of opium in the United States Pharmacopœia. The Edinburgh College substituted a similar preparation under the name of the electuarium thebaicum. On the Continent, however, theriaca long survived. SAVIGNAC—p. 415, *op. cit.*, p. 620, *supra*—remarked, with some sarcasm, that under the name of thériaque it still figured in the French Codex, vipers' flesh and all, and hoped it would soon be banished. But it can be seen unmodified in the revised Codex of 1866, p. 506. Now the iatro-chemists conceived the unhappy idea of making a distilled water out of this famous compound which should represent its quintessence: and not content with its complexity they added, each according to his fancy, numerous other ingredients to the mixture introduced into the still. The resulting aqua theriacalis was named after its compounder, so that we read, for example, in VALERIUS CORDUS—p. 170 *et seq.*, *op. cit.*, *supra*—of the aqua theriacalis Lugdunensis, the aqua theriacalis Sylvii and the aqua theriacalis Rondeletii; and various other formulæ are given by QUERCETANUS—p. 24 *et seq.*, *op. cit.*, *supra;* VIDUS VIDIUS—p. 225, *cap. cit.*, *supra;* NICOLAS LEMERY—p. 528 *et seq.*, *op. cit.*, *supra*—and others. The aqua theriacalis of the London Pharmacopœia of 1677—p. 32, Ed. cited, *supra*—contained no less than nine herbs, leaves, roots and juices, besides theriaca and a modification of the antidote of MITHRIDATES, (imitated from the Galenical preparation of that name and containing almost as many ingredients as theriaca; see p. 100, *op. cit.*) The older iatro-chemists depended upon the drugs introduced into the still for the virtues of the product, but after a time Canary and other wines were added, as in the formula of the London Pharmacopœia, and at a later date French brandy in such quantities that the product must have been rich in alcohol. For example, JOHN QUINCY—p. 9, *op. cit.*, *supra*—gives the formula as follows: "*Aqua Theriacalis. Treacle Water.* Take of the juice of green walnuts four pints; of the juice of rue three pints; of carduus and baum, each two pints; of the fresh gathered butter-bur roots one pound and an half; of burdock one pound; of angelica and master-wort, each half a pound; of green scordium four handsful; of old Venice treacle (*i. e.*, theriaca) and Mithridate, each eight ounces; of lemon juice two pints; of French brandy one gallon and an half. Draw off by distillation three gallons and an half, and then add four pints of distilled vinegar." The confidence reposed for more than two hundred years in the sudorific as well as the alexipharmic virtues of these comparatively inert distillates is well indicated by the passages cited from RIVERIUS in note ‡, and DOLÆUS in note §, last page. It would be easy to multiply such citations did space permit.

* I suppose the "potus pestilentialis" referred to by DOLÆUS, in the passage just cited, includes the whole group of compound distilled waters which the iatro-chemists supposed to act as sudorifics and antidotes in plague and other pestilential diseases, such as the aqua vitæ of Arnold de Villanova, described by VALERIUS CORDUS—p. 170, *op. cit.*, *supra*—the aqua ad pestis curationem et præservationem, and aqua ad febres pestilentes of QUERCETANUS—p. 33 *et seq.*, *op. cit.*, *supra*—and the various similar nostrums invented by others. For the most part, whatever herbs were put into the still in preparing these distillates, theriaca or Mithridate, or both, were added also, so that in their general character these were akin to the treacle waters. One of the most celebrated of them was the aqua epidemica or plague water of the London Pharmacopœia, which I mention because its use in dysentery was sanctioned by the authority of SYDENHAM—*Med. Obs.*, Sect. IV, Cap. 3, Vol. I, p. 171, *op. cit.*, p. 407, *supra*. This water was prepared without theriaca or Mithridate by distilling a mixture of roots or herbs with white wine or brandy. Several different formulæ were used: for that of the London College, see the Pharmacopœia of 1677, p. 29, cited *supra*. The formula of BATE, which long enjoyed great credit among the English physicians, is thus given by WILLIAM SALMON—*Pharmacopœia Bateana: or, Bate's Dispensatory*, London, 1694, p. 12—"*Aqua Epidemica, The Plague-Water.* [Bate.] ℞. Celandine rosemary, rue, sage, mugwort, worm-wood, pimpernel, dragons, scabiouse, agrimony, baum, scordium, lesser centory, cardnus benedictus, betony, ros solis, of each two handfuls: Roots of angelica, tormentil, gentian, zedoary, liquorice, of each one ounce. Macerate in white wine lb viii, for two days, then distil according to art." SALMON adds the following interesting remark: "In my opinion, if three or four good large lemons were thin sliced and put (after distillation) into the water, it would be so much the better, for that the particles of that acid juice certainly destroy all the vermiculi, or miasmata, which are the progenerators of the plague, or pestilence; and also more powerfully overcome it when the infection is begun. For this reason it is, vinegar is put into almost all our plague-waters, by Sylvius, Barbet, and others of the more learned physicians." In concluding this note I must refer to the aqua dysenterica of QUERCETANUS—p. 38, *op. cit.*—which was distilled from a great variety of drugs, including myrobalans, opium and a large proportion of the astringents and aromatics at that time used in dysentery. It is mentioned by SENNERTUS—T. III, p. 179, *op. cit.*, p. 645, *supra*—in connection with several other antidysenteric distilled waters invented by various physicians. As late as the beginning of the eighteenth century a distilled aqua antidysenterica is described by NICOLAS LEMERY—p. 583, *op. cit.*, last note.

† SYLVIUS—*De Meth. Med.*, Lib. II, Cap. 11, Opera, p. 107, Ed. cited p. 690, *supra:* "Hoc imprimis verum de opio, cujus præsertim ratione sudores movent omnia opiata."

treatment of the fluxes.* In this he was followed by Hoffmann, who attached great importance to the action of diaphoretics in dysentery, especially in its malignant and epidemic forms.† About the same time Freind, having observed that ipecacuanha often excited a profuse sweat, suggested that it owed its efficacy in dysentery to this circumstance,‡ and Wilson subsequently drew attention to the fact that this operation of ipecacuanha was rendered much more energetic and certain when opium was added.§ The employment of this combination or of some preparation of antimony alone or with opium, in the treatment of dysentery, speedily came into common use.

Degner, indeed, protested against resorting to diaphoretics in dysentery,‖ and Stoll expressed the opinion that the cases reported to have been cured by diaphoretic antimony, broken doses of ipecacuanha and opium and other sudorifics, could have been only simple uncomplicated cases of rheumatismal (catarrhal) dysentery;¶ but these remedies nevertheless continued to be very generally employed, though for the most part in subordination to purgation and other more active measures. Moseley, however, went so far as to vaunt diaphoresis as the most important part of the treatment of dysentery, relying upon James's powder, glass of antimony or even ipecacuanha for the purpose. His extravagant views obtained few followers,** yet the use of diaphoretics in dysentery has continued to find advocates to the present time. Tartar emetic in broken doses†† has for the most part

* SYLVIUS—*Praxeos*, Lib. I, Cap. 13, p. 183, *op. cit.* The antimonium diaphoreticum enters into one of the formulæ he advises for the treatment of purulent or sanious fluxes, and he commends opium in the treatment of dysentery. In *De Meth. Med.*—*loc. cit.*, last note—he commends as sudorifics not only antimonium diaphoreticum, but Bezoardicum minerale. The first was prepared by igniting together antimony and nitre, a white hard mass being thus formed, which was subsequently powdered and thoroughly washed with hot water until no taste of the nitrous salt remained. See BOERHAAVE'S *New Method of Chemistry*, English Transl., 2d Ed., London, 1741, Vol. II, p. 339. This preparation dates back to BASIL VALENTINE—p. 113, *op. cit.*, p. 689, *supra*—but it was also used without washing, and was then known as the diaphoretic antimony with nitre. BOERHAAVE—*loc. cit.*—preferred it unwashed, declaring the common or washed preparation to be "an indolent, noxious calx, without any activity discoverable by observation." It has, however, held its ground, and I find in the French Codex of 1866, p. 150, a formula for an antimoine diaphorétique lavé, which differs only in the proportion of the ingredients from that of BASIL VALENTINE. The Bezoardicum minerale was so called because its virtues were supposed to be similar to those attributed to the Bezoar stone: see note ‡, p. 729, *supra*. JOHN QUINCY—p. 246, *op. cit.*, last page—states that it was originally the contrivance of CROLLIUS. It was prepared in various ways by different chemists, a common method being the action of spirits of nitre (nitric acid) on butter of antimony. This is the method directed in the London Pharmacopœia of 1677, p. 189, Ed. cited p. 729, *supra*. It is interesting to note the substances commended by SYLVIUS for their diaphoretic virtues in the chapter just cited, viz: A number of merely aromatic herbs, as well as guaiac wood, sassafras wood, juniper wood, the leaves and seed of carduus benedictus, &c.; then various volatile salts; the Eastern and Western Bezoar stones; and besides the opiates and antimonials mentioned above, the mercurius præcipitatus diaphoreticus, which he directs to be prepared by the addition of oil of tartar to a solution of corrosive sublimate in water, and given in the dose of 4 to 6 grains. The mercurius præcipitatus diaphoreticus was originally invented by PARACELSUS, in whose treatise—*De Natura Rerum*, Lib. V, T. II, p. 94, *op. cit.*, p. 336, *supra*—an account of his method of preparation will be found. This method, that given by J. BEGUIN—*Tyrocinium Chymicum*, (1614;) I cite the Ed. of Wittenberg, 1650, p. 322—and that described by SYLVIUS differ considerably, a question into which my space does not permit me to enter; but the mercurius diaphoreticus is worthy of mention here, although it has long since gone out of use, because of the employment of other preparations of mercury as diaphoretics in quite modern times. In this place I may speak of the practice of WILLIS—p. 81 *et seq.*, chapter cited p. 680, *supra*—who gave diaphoretics the first place in the treatment of the London dysentery, but held fast to the treacle of ANDROMACHUS, prepared coral and prepared pearl, variously combined with the so-called sudorific herbs, &c., and with preparations of opium, instead of venturing to give his dysenteric patients the Bezoar mineral and diaphoretic antimony, which he commends loudly enough in his chapter on the general subject of diaphoretics—Sect. V, Cap. 2, p. 122 *et seq.*, *op. cit.*—to which I refer the reader for a curious list of the substances he believed to possess diaphoretic properties.

† FRID. HOFFMANN—*Med. Rat. Syst.*, pp. 156 and 158, chapter cited p. 681, *supra*. He recommended that they should be admixed with absorbentia, and gives quite a list of the substances that may be thus used.

‡ J. FREIND—*De Febribus Commentarii Novem*, (1717,) Comm. IV; I cite Opera, London, 1733, p. 253. This suggestion appears to have made a great impression at the time, if I may judge from the manner in which it is discussed by BAKER—p. 27, *op. cit.*, p. 437, *supra;* AKENSIDE—p. 40, *op. cit.*, p. 681, *supra;* MOSELEY—p. 220, *op. cit.*, p. 648, *supra*, and others.

§ WILSON—p. 33 *et seq.*, *op. cit.*, p. 681, *supra*—in consequence of his peculiar views of the nature and causation of dysentery, attached great importance to the use of sudorifics in the treatment. He employed them especially to resist the "tendency of the blood to solution." He commended the spiritus Mindereri, and those diaphoretics "which are also called alexipharmics, cardiacs, or antiseptics;" but especially emphasized "the certain effect which an anodyne has of converting ipecacuan. into a powerful diaphoretic," p. 45. I may note here that AKENSIDE—*loc. cit.*—writing three years later, although he admitted that ipecacuanha conjoined with opium elicited more abundant sweats than any other sudorific, objected to this mode of treatment, lest the patient should take cold by going frequently to stool while sweating, and therefore gave the ipecacuanha without opium in grain doses every six hours, claiming that it altered the condition of the intestines without causing either vomiting or sweating.

‖ DEGNER—Cap. V, § 23, p. 279, *op. cit.*, p. 625, *supra*. ¶ STOLL—Cap. 2, p. 252 *et seq.*, *op. cit.*, p. 342, *supra*.

** MOSELEY—p. 219 *et seq.*, *op. cit.*, p. 648, *supra*. With regard to glass of antimony and cerated glass of antimony, see p. 690, *supra*. James's powder, of late years described in the British Pharmacopœia as pulvis antimonialis, is a mixture of one part of oxide of antimony with two of precipitated phosphate of lime. Among those who most heartily embraced the views of MOSELEY I may mention HARTY—p. 178 *et seq.*, *op. cit.*, next page.

†† Among those who have employed broken doses of tartar emetic or antimonial wine for this purpose, I may mention WADE—*op. cit.*, p. 706, *supra;* RICHTER—*Med. u. Chir. Bemerk.*, Bd. I, Gottingen, 1793, S. 99; CHRISTIE—*op. cit.*, p. 706, *supra;* ANNESLEY—Vol. II, p. 280, *op. cit.*, p. 621, *supra;* and G. B. WOOD—Vol. I, p. 721, *op. cit.*, p. 671, *supra*—who, however, limited their employment to cases in which the skin was hot and dry. I would remark that in this and subsequent notes I have made no attempt to present a complete list of authorities, but merely cite a few of the prominent advocates of each measure.

replaced the use of other antimonials for this purpose, and ipecacuanha has been very generally given in the form of Dover's powder.* The old notion of the diaphoretic action of mercury, revived by Harty, has been accepted by some who claim this, among other benefits, from the use of calomel or blue mass in broken doses especially when combined with opium and ipecacuanha.† The solution of acetate of ammonia and the solution of citrate of potash have also had their advocates.‡ The use of the hot bath, long ago employed in dysentery by Alexander of Tralles, has also found favor, some even going so far as to attribute to it the power of jugulating the disease in its early stages.§ Hot vapor baths, dry heat and alcoholic fumigations have also been commended.‖

On the other hand, serious objections to the use of diaphoretics in dysentery have been urged during the present century. Some have emphasized the danger of taking cold while going to stool, others have pointed out that most of the substances employed as diaphoretics are irritating to the intestinal mucous membrane; moreover, the alleged beneficial effect of diaphoresis upon the progress of dysentery has been doubted or altogether denied.¶ As a consequence their employment has become less and less general, and several of the best modern writers on dysentery, as Trousseau, Barrallier and Maclean, do not even discuss the use of medicines of this class.** During our own civil war Dover's powder was sometimes given as a diaphoretic, but other sudorifics were little used.††

* Dover's powder, as first described by THOMAS DOVER (DOVAR in this Ed.)—*The Ancient Physician's Legacy to his Country*, London, 1733, p. 11—who employed it in the treatment of gout, consisted of one part each of opium, ipecacuanha and powdered liquorice, and four parts each of nitre and vitriolated tartar, (sulphate of potassa.) As is well known, both the British and United States Pharmacopœias omit the nitre and liquorice, using one part each of opium and ipecacuanha to eight of sulphate of potassa, while the French Codex retains the formula of Dover, with the exception that the extract of opium is substituted, so that the resulting preparation is more active in this ingredient. Among the prominent advocates of the diaphoretic use of ipecacuanha and opium in dysentery may be mentioned PRINGLE—p. 263, *op. cit.*, p. 640, *supra*—who, in his later practice, substituted this combination for the cerated glass of antimony; GILBERT BLANE—Part III, Chap. 2, p. 455, *op. cit.*, p. 637, *supra;* ANNESLEY—Vol. II, p. 280, *op. cit.*, p. 621, *supra;* BANKIER—p. 191 *et seq.*, *op. cit.*, p. 637, *supra;* and more recently NIEMEYER—Bd. II, S. 755, *op. cit.*, p. 645, *supra;* JACCOUD—T. II, p. 341, *op. cit.*, p. 649, *supra;* AITKEN—Vol. II, p. 660, *op. cit.*, p. 647, *supra;* and STILLÉ—p. 354, *op. cit.*, p. 650, *supra.*

† WILLIAM HARTY—*Obs. on the simple Dysentery and its Combinations*, London, 1805, p. 192 *et seq.* Among those who have shared these views I may particularly mention ANNESLEY—Vol. II, p. 279, *op. cit.*, and BANKIER—p. 194, *op. cit.*

‡ The liquor ammoniæ acetatis, formerly known as the spirits of Mindererus, figures among the diaphoretics commended by WILSON—*loc. cit.*, note §, last page; DONALD MONRO—p. 75, *op. cit.*, p. 625, *supra;* BANKIER—*loc. cit.*, note *, *supra*, and many modern writers. The citrate of potassa was formerly known as the salt of Riverius. I find a formula for its extemporaneous preparation in *The Edinburgh New Dispensatory*, 2d Ed., 1789, p. 540, borrowed from the *Pharmacopœa Succica*, Ed. alt., Stockholm, 1779, which I have not seen. It is described as the "mixtura salina, saline mixture or julep," and directed to be made by adding lemon juice and simple syrup to a solution of fixed vegetable alkali in water. The remark is appended that it is in daily use as a gentle diaphoretic among British practitioners. WADE—*loc. cit.*, note ††, last page—describes it as the neutral mixture, and used it with the addition of two, three or more grains of tartar emetic to the pint as a diaphoretic in dysentery. The use of this combination or of the neutral mixture is commended by many subsequent writers.

§ ALEXANDER OF TRALLES—Lib. VIII, Cap. 9, p. 460, Ed. cited p. 624, *supra:* "Adhæc utatur æger maxime inter initia balneo crebriore, et calidiore solio, magisque, si aquæ potio et frigidorum ciborum esus præcesserit, ac pituitæ suspicio sit." BAKER—p. 34, *op. cit.*, p. 437, *supra*—relates the case of a patient, who, having been sick with dysentery a whole week, was speedily cured by a warm bath. FOURNIER et VAIDY—p. 386, *op. cit.*, p. 362, *supra*—reported that they frequently saw, in the French army, officers reduced to a desperate condition by dysentery, who owed their recovery chiefly to warm baths; and remarking that under such circumstances soldiers almost always die, suggested that proper conveniences for the administration of warm baths should be furnished at every military hospital; a suggestion with which I heartily concur, although for other reasons. Among those who have highly praised the use of the warm bath in dysentery I may mention our own BENJAMIN RUSH—*Med. Inquiries and Obs.;* I cite the 2d Ed., Philadelphia, 1794, Vol. I, p. 260—who remarked that the dysentery, prevailing in the summer of 1777 in the military hospitals in New Jersey, "was frequently followed by an obstinate diarrhœa, in which the warm bath was found in many cases to be an effectual remedy." See, also, HARTY—p. 183, *op. cit.*, *supra;* ANNESLEY—Vol. II, p. 281, *op. cit.*, p. 621, *supra;* NAUMANN—Bd. IV, Abth. 2, S. 80, *op. cit.*, p. 645, *supra;* and SAVIGNAC—p. 334, *op. cit.*, p. 620, *supra*—who, however, on account of the inconvenience of general baths, gives the preference to warm hip-baths, in which, to increase their soothing effect, he sometimes infused the leaves of solanum nigrum (morelle) or belladonna.

‖ With regard to the first two of these measures, see COPLAND—Vol. I, p. 729, *op. cit.*, p. 682, *supra.* Fumigations with vapor of alcohol have been especially commended by SAVIGNAC—p. 336, *op. cit.*, last note—in cases of chronic dysentery. He introduces the patient into a closed space of wood or waxed cloth, from which his head only projects, and into which the fumes of a large alcohol lamp are conveyed through a tin tube. These vapors consist largely of vapor of water, which, however, carries some volatilized alcohol with it. The patient remains in the bath fifteen or twenty minutes.

¶ The danger of taking cold while rising for stool has been emphasized, among others, by MOREHEAD—p. 302, *op. cit.*, p. 657, *supra.* Of course it would be avoided if the rule laid down on p. 656, *supra*, were strictly observed. Among those who have pointed out that the medicaments relied upon as diaphoretics are for the most part irritating to the intestinal mucous membrane, NAUMANN—Bd. IV, Abth. 2, S. 81, *op. cit.*, p. 645, *supra*—may be mentioned. Doubts as to the curative effects claimed for diaphoretics are expressed by BAMFIELD—p. 128, *op. cit.*, p. 682, *supra;* and ROCHE—p. 355, *op. cit.*, p. 725, *supra*—declares that their reputation for efficacy has not been well established.

** TROUSSEAU—*op. cit.*, p. 664, *supra;* BARRALLIER—*op. cit.*, p. 603, *supra;* MACLEAN—*op. cit.*, p. 657, *supra;* HEUBNER—*op. cit.*, p. 529, *supra.* It would be easy to add to this list.

†† Among the reporters in Section II, BROWN—p. 77, *supra;* JONES—p. 85, *supra;* and TAYLOR—p. 87, *supra*—commended the use of Dover's powder. SCHÜSSLER—p. 44, *supra*—praised solution of acetate of ammonia combined with laudanum. WHITE—p. 85, *supra*—prescribed "diaphoretics" in combination with calomel; and PENROSE—p. 45, *supra*—who attached great importance to "attention to the condition of the surface" in chronic dysentery, commended the use of frequent hot baths.

I am myself inclined to agree with those who doubt whether any material effect upon the progress of dysentery or the other fluxes can be obtained in this way. The antimonials should, I think, be rejected for the reasons already given. Whatever benefit may result from the use of ipecacuanha seems to depend upon its influence on the intestinal mucous membrane rather than its action on the skin. The question of the use of opium will be discussed further on; but it may be remarked here that its diaphoretic operation is probably the least important circumstance to be considered in determining whether it shall be used in any particular case. As for the other diaphoretic medicines, they should be avoided as likely to perturb the stomach or intestines without equivalent benefit. Nor do I view with favor the use of the hot bath in acute dysentery, though hot bricks or bottles of hot water may sometimes be advantageously applied when the extremities are cold, and during the stage of collapse. In chronic fluxes, however, when the skin is dry or covered with furfuraceous scales, the warm bath may be resorted to with benefit.

DIURETICS.—The ancient physicians paid even more attention to the use of diuretics in the treatment of the fluxes than they bestowed upon sudorifics. Diocles of Carystus, who flourished shortly after Hippocrates, directed their use in dysentery partly that the superabundant moisture of the body might be dried up, partly on account of their effect in relieving the troublesome vesical symptoms.* It was one of the general principles of the humoral pathology, as taught by Galen,† that peccant humors might be evacuated from the body by remedies which promote the secretion of urine; and this mode of diverting the materies morbi from the alimentary canal in dysentery was formally commended by Celsus and some of the later Greeks, as well as by the Arabian writers. Celsus, however, insisted that diuretics should be administered in this disease to such patients only as previous experience had shown to be readily affected by their operation, alleging that if they failed to act on the kidneys they aggravated the flux.‡

Many subsequent physicians, until after the beginning of the eighteenth century, adopted diuretics as a part of their routine in the treatment of dysentery, but for the most part cautioned against giving them early in the disease, before the free use of purgatives or other evacuants had diminished the abundant morbid humors, alleging imaginary dangers in explanation of this precaution.§ During the eighteenth century, however, the use of

* I find no direct mention of the use of diuretics in the Hippocratic writings, but the following passage seems to hint at their employment in lientery: "This disease needs treatment until the urine flows in proportion to the drink taken, the body is nourished by the food ingested, and it is freed from its bad color," *Prædictorum*, Lib. II, § 23, [Ed. Littré, IX, 53.] The teachings of DIOCLES on this subject have been preserved by CÆLIUS AURELIANUS in his chapter on Ventriculosa Passio, or Cœliacus—*Morb. Chron.*, Lib. IV, Cap. 3, p. 521, Ed. cited p. 664, *supra:* "DIOCLES quoque libro quo de passionibus atque causis, et curationibus scripsit, providens siccandum corpus, urinalibus medicaminibus utendum jubet, quibus non solum humor ventris siccari minime posse perspicitur, verumetiam vesica in morbos ægi invenitur." GRUNER—*Bibliothek der Alten Aerzte*, Theil II, Leipsic, 1782, S. 623—understands this passage to refer to the treatment of the cœliac affection, and most of those who have cited it take the same view on account of the subject of the chapter in which it is preserved; I must, however, agree with HALLER—*Bibl. Med. Pract.*, T. I, Basel, 1776, p, 111—in understanding it to refer to dysentery; for in this disease the bladder is frequently involved, as DIOCLES observed, which is rarely the case in the cœliac flux.

† For the authorization of the use of diuretics for this purpose by GALEN, see note ‡, p. 728, *supra*. I have, however, found no specific directions in his writings for the administration of the diuretics in dysentery.

‡ CELSUS, in his chapter on dysentery—Lib. IV, Cap. 15, Vol. I, p. 297. Ed. cited p. 656, *supra*—wrote as follows: "But these things which promote the urine have a good effect, if they succeed, by determining the fluids into another part; if they do not, they increase the mischief: therefore they must not be administered, except to those on whom they have been accustomed to produce that effect readily." Among the later Greeks ÆTIUS—Tetrab. III, Serm. 1, Cap. 47, p. 609, Ed. cited p. 656, *supra*—commends diuretics [alia etiam urinam ciendo] in both dysentery and the cœliac flux; PAULUS ÆGINETA—Lib. III, Cap. 40, Vol. I, p. 521, Ed. cited p. 624, *supra*—strongly recommends them in the cœliac flux and lientery; and ACTUARIUS—*Medicus, sive De Meth. Med.*, Lib. IV, Cap. 6; I cite the Latin version of MATHISIUS in the *Med. Artis Principes* of H. STEPHANUS, Paris, 1567, p. 226—in the alvine fluxes generally. A list of the medicines regarded as suitable for this purpose, such as parsley, maiden hair and various compounds, is given by PAULUS—*loc. cit.* The views of the Arabians on the subject are summarized in the passage cited from AVICENNA in note §, p. 689, *supra*.

§ Thus ALTOMARUS—*loc. cit.*, p. 689, *supra*—repeats with approval the opinions of CELSUS and ÆTIUS. FORESTUS—*loc. cit.*, p. 689, *supra*—in like manner cites CELSUS, but counsels that the use of diuretics be postponed till after the first few days of the disease, lest in moving such an abundance of morbid humors the narrow passages through which they pass should be ulcerated. (What narrow passages he meant may be inferred from the explanations of HILDANUS and SENNERTUS, cited below.) FELIX PLATER—*loc. cit.*, p. 689, *supra*—did not allude to this supposed danger, but counselled, without reservation, that a part of the morbid humors should be evacuated through the urinary organs, and advised for this purpose a mixture containing the four greater cold seeds (viz: cucumber, pumpkin, gourd and muskmelon) with the seeds and root of asparagus, &c. FAB. HILDANUS—*loc. cit.*, p

diuretics in the fluxes fell into disuse, and few modern writers appear to attach much importance to their administration in these disorders.

It may readily be admitted that the indications for remedies of this class afforded by the humoral pathology are no longer valid, and that although the relation between the functions of the kidneys, bowels and skin is as fully recognized now as in the early days of Greek medicine, we possess no satisfactory evidence that the induction of an increased secretion of urine can, of itself, exercise any perceptible effect on the progress or duration of an inflammatory process affecting the intestinal mucous membrane. Nevertheless the marked diminution in the quantity of urine, sometimes amounting almost to complete suppression, as well as the strangury and vesical tenesmus so common in acute dysentery, seem to afford an indication for the employment of diuretics. The first of these symptoms, which is often connected with a condition of the kidneys more serious than mere functional disorder,* must cause more or less accumulation of urea in the blood, a part of which is likely to be excreted by the bowels, and, breaking up into carbonate of ammonia, to aggravate the intestinal lesions.† Moreover, the scanty urine in this condition is often highly acid and likely to perturb the irritable urinary bladder.

Yet the dictum of Degner, that when diminished secretion or even suppression of urine occurs in dysentery it requires no treatment unless accompanied by vesical tenesmus or strangury, appears to have been generally accepted; and even for the relief of local symptoms the employment of diuretics has found few modern advocates.‡ For myself, I favor their use not only on this account, but also with the deliberate object of increasing the secretion of the kidneys whenever it is notably diminished; I would suggest the bitartrate of potash, which, in laxative doses, produced such beneficial results in the hands of Zimmermann and Cheyne, or acetate of potash, which Coues found so efficacious in relieving vesical tenesmus; possibly, also, atropia may sometimes prove useful for this purpose, as will be shown further on.§ Other diuretics may perhaps be substituted with equal advantage,

680, *supra*—advises that diuretics should be administered only after thorough purgation, otherwise he says the acrid and malignant humor, while it passes through the mesenteric veins and liver on its way to the kidneys, may injure those important organs. He commends as a diuretic the roots of parsley, fennel and anise boiled with flesh, and the broth given an hour before each meal. In Cap. 19, p. 695, *op. cit.*, he directs the use of various hip baths, clysters, &c., to relieve the retention of urine and vesical tenesmus, or even diuretics if necessary, but with the caution already mentioned. SENNERTUS—*loc. cit.*, p. 689, *supra*—expresses very similar views, and repeats the same warnings. BOERHAAVE—*Aph.* 722, and VAN SWIETEN—T. II, p. 395, *op. cit.*, p. 663, *supra*—advises diuretics in dysentery for the purpose of diverting the humors from the intestine, without alluding to these imaginary dangers.

* See pp. 460 and 560, *supra*.

† Compare the views of TREITZ and ZIMMERMANN, cited p. 386, *supra*, with the suggestion of VIRCHOW, discussed on p. 631, *supra*, as to the part played by ammoniacal compounds liberated in the alimentary canal in transforming simple catarrhal inflammation into diphtheritic dysentery.

‡ DEGNER—Cap. 3, § 72, p. 184, *op. cit.*, p. 625, *supra*—remarked: "Ubi urinæ suppressio aderat, nec tamen illa incommodi quidquam pariebat, nulla indigebat medela;" but when vesical tenesmus, or dysuria or strangury, which he attributed to sympathy (consensus) between the neck of the bladder and the rectum, was present, he gave balsamum sulphuris simplex or anisatum in decoction of simaruba, which he declared produced admirable results, especially at the beginning of the disease. The balsamum sulphuris simplex was made by heating one part of flowers of sulphur with four of olive oil, and the bals. sulph. anisatum by boiling flowers of sulphur with oil of anise in the same proportions: see JOHN QUINCY'S *Compleat English Dispensatory*, 12th Ed., London, 1749, Part II, pp. 25 and 26. J. G. RADEMACHER—*Libellus De Dysenteria*, Cologne, 1806, p. 147—in discussing the difficulty of urination, which he declares is a most common accident in dysentery, remarks that the kidneys also are often sympathetically involved, as shown by the diminution of the secretion, which is often insufficient in quantity to distend the bladder, although the patient does not urinate for a whole day; but he remarks that it is vain to administer diuretics, and that they are unsuitable or, if they augment the intestinal movements, injurious. He also objected to the use of diuretics for the relief of vesical complications, and advised warm applications to the lower part of the abdomen instead. He rarely observed actual retention of urine during the epidemic at Cleves, but in one patient, an old man, in whom this symptom was so troublesome that the frequent use of the catheter was required, relief was at length obtained by the administration of the flour of lycopodium, two drachms in six ounces of syrup; dose a tablespoonful every hour. SCHWEICH—S. 403, *op. cit.*, p. 717, *supra*—also commended lycopodium, which he combined with emulsion of flaxseed or sweet almonds for this purpose. PARKES—p. 147, *op. cit.*, p. 682, *supra*—merely advises the warm bath or cold water injections for the relief of the vesical symptoms in dysentery; and VOGT—S. 219, *op. cit.*, p. 645, *supra*—thought warm emollient drinks and fomentations quite sufficient, unless there was actual retention, in which case he employed warm soda baths followed by narcotic cataplasms or fomentations and the use of the catheter if necessary; he also praised the internal administration of belladonna as preferable to opium in these cases. On the other hand, a few physicians have recommended diuretics when the urine is scanty; as for example BAMPFIELD—p. 163, *op. cit.*, p. 682, *supra*—who remarks: "When the strangury, ardor urinæ, etc., are caused by the paucity of urine or its acrimony, the patient should be encouraged to drink plentifully of mild mucilaginous and demulcent diluents; should be ordered some diuretic, by which the urinary secretion may be promoted and increased, and fomentations should be employed from the abdomen to the nates." In this connection I may refer to the suggestion of MOREHEAD—p. 284, *op. cit.*, p. 657, *supra*—that retention of urine very often results from inflammation of the peritoneal coating of the bladder, as a hint worthy of consideration.

§ For the experience of ZIMMERMANN and CHEYNE, see the passages cited note ‖, p. 707, *supra;* for the practice of COUES, see p. 63, *supra*.

but care should be taken to avoid those that are likely to irritate the inflamed intestines. That any benefit is to be expected in the fluxes from remedies of this class, except for the purposes just indicated, may be admitted to be highly improbable.

OPIUM AND ITS PREPARATIONS.—A knowledge of the anodyne and soporific virtues of certain plants, especially the poppy, probably dates back to prehistoric times; and their use for the relief of the pain that so often accompanies the fluxes must be equally old.* It is true that the Hippocratic writings are silent as to this application of narcotics, but it must be remembered that the Hippocratic treatise on Pharmacy, in which it might be expected to be discussed, has unfortunately been lost.† We have, however, the testimony of Cælius Aurelianus that Diocles of Carystus used the juice of the poppy combined with nutgalls in the treatment of dysentery.‡ When Galen wrote, the liberal use of opium, hyoscyamus and other anodynes in the treatment of all painful fluxes was already the general practice, as is shown by the numerous often very complex formulæ, both for administration by the mouth and the rectum, which he has handed down.§ Similar formulæ have been preserved by Ætius, Alexander of Tralles and Paulus Ægineta;|| but it is worthy of note that Celsus is silent with regard to the use of anodynes in the fluxes, and that Galen expressly cautions against the danger of using them in excessive quantities.¶

Alexander of Tralles, in a remarkable passage, declared that unskilful physicians fall into the error of giving pastilles of opium, hyoscyamus, mandrake and other anodynes in dysentery for the purpose of relieving the pain by sleep, but that after the patient has slept with apparent benefit through the night, it will be found he passes next morning the great quantity of humors meanwhile accumulated, suffers with headache and loss of strength, and that his flux is made worse; for himself, he thought such medicines should never be given except when strong necessity urges.** The Arabian physicians exercised similar caution.

* Thus, in the *Odyssey*, Lib. IV, 219-226, HOMER relates that Helen gave Telemachus a sorrow-lulling (*νηπενθές*) drug, (*φάρμακον,*) which had the property of producing forgetfulness and sleep. He adds that she obtained it from Polydamna, wife of Thon, an Egyptian; and that Egypt produces many powerful drugs, some excellent and others poisonous. It seems to me more reasonable to agree with SPRENGEL—Bd. I, S. 93, *op. cit.*, p. 346, *supra*—and others that the drug referred to was opium or some other narcotic, (thus CHRISTEN—I cite from the review of his *History of Opium* in the Edinburgh Jour. of Med. Sci., Vol. II, 1826, p. 371—thinks it was Indian hemp,) than to suppose with JOHN J. OWEN—Notes to his edition of the *Odyssey*, New York, 1872, p. 407—that the description is "put allegorically for the charm of attractive conversation by which grief is banished insensibly from the mind."

† The lost book is mentioned in the Hippocratic treatise *De Affectionibus*, § 23, [Ed. Littré, VI, 235.] where, in connection with the treatment of dysentery, we are told that further particulars with regard to the drinks, broths and food, are written in the book on Pharmacy, (*ἐν τῇ φαρμακίτιδι*;) or, as KÜHN—T. II, 401—translates it, "prout in medicamentorum tractatione scriptum est." The use of the juice of the poppy as an anodyne was, however, well known at this time, as may be seen from several passages in the Hippocratic writings: see, for example, the treatise *De Morbis Mulierum*, Lib. II, § 201, [Ed. Littré, VIII, 387,] where mention is made of the juice of the poppy and of the sleep-producing poppy, (*ὀπὸς μήκωνος* and *ὑπνωτικὸν μηκώνιον.*) A description of the mode of collecting opium from the poppy capsules, and a declaration that the extract made from the entire plant is less active, will be found in DIOSCORIDES—Lib. IV, Cap. 65, Fol. 213 *et seq.*, *op. cit.*, p. 623, *supra.*

‡ CÆLIUS AURELIANUS—*Morb. Chron.*, Lib. IV, Cap. 6, p. 526, Ed. cited p. 664, *supra*—relates that DIOCLES, in his book *De Passionibus et earum Causis et Curationibus*, directed galls with opium among other remedies for the treatment of dysentery.

§ See, especially, *De Comp. Med. secundum Locos*, Lib. VII, Cap. 5, [Ed. Kühn, XIII, 88.] in which there are a number of such formulæ, generally described as "anodynes," and vaunted for their efficacy in dysentery and the cœliac flux, as well as in other disorders. Others will be found in Caps. 3 and 4 of the same book, and in Lib. IX, Cap. 5, same Vol. Many of them are professedly borrowed from the writings of his predecessors, whose names are given. As an example of their character I may cite the preparation called "Aster," Lib. VII, Cap. 5, p. 91: "℞ Croci obol. iij, seminis hyoseyami ʒvj, seminis apii ʒvj, anisi ʒiiij, styracis ʒiiij, seminis dauci ʒiiij, castorii ʒij, opii ʒiij, myrrhæ ʒij, quidam etiam mandragoræ succi ʒiiij, ut vero Xenocrates, etiam piperis albi ʒvj, cum aqua fac pastillos triobolares. Dato ex aqua." I have already referred to GALEN'S account of those marvels of polypharmacy, the antidote of MITHRIDATES and the theriaca of ANDROMACHUS, (see notes to p. 730, *supra,*) which for centuries after his time were prescribed in the fluxes. Another compound, which shared in some degree this renown, was the antidote of PHILO, or Philonium, which PHILO described in a poem preserved by GALEN—Lib. IX, Cap. 4, p. 267 *et seq.*, volume cited. It contained opium, hyoscyamus, white pepper, crocus, &c. In various modified forms this preparation long survived in pharmacy. LEMERY—p. 422 *et seq.*, *op. cit.*, p. 729, *supra*—gives formulæ for several such compounds. Its use in dysentery is referred to by PISO, MERCURIALIS, SENNERTUS (see places cited in note †, next page) and other writers of the 16th and 17th centuries.

|| ÆTIUS—Tetrab. III, Serm. I, Cap. 48, p. 669, Ed. cited p. 656, *supra.* ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 445 *et seq.*, and Cap. 9, p. 467 *et seq.*, Ed. cited p. 624, *supra.* PAULUS ÆGINETA—Lib. III, Cap. 42, Vol. I, p. 526, Ed. cited p. 624, *supra.*

¶ Yet CELSUS was well acquainted with opium, which he called lachrimæ papaveris, and did not hesitate to prescribe it in colic: see Lib. IV, Cap. 14, Vol. I, p. 295, Ed. cited p. 656, *supra.* GALEN—*Meth. Med.*, Lib. XII, Cap. I, [Ed. Kühn, X, 816.]—is exceedingly emphatic with regard to the indiscriminate use of anodyne remedies. (He specifies the juice of the poppy, hyoscyamus seeds, mandrake root and styrax.) Those, he cries, who resort to these remedies at improper times or immoderately, jugulate the sick along with their pains. I have already referred to the evil consequences which GALEN attributed to the rash suppression of the dysenteric discharges: see note †, p. 411, *supra.* Similar sentiments were entertained by PHILUMENUS, in ÆTIUS—Tetrab. III, Serm. I, Cap. 35, p. 585, Ed. cited p. 656, *supra:* "Etenim obluctari et excretionis cohibitionem moliri, majorem morbum facit: siquidem quæ cohibentur sursum perlata dolores capitis, aut phrenitidas, aut lethargos, aut parotidas inferunt plane perniciosos."

** ALEXANDER OF TRALLES—Lib. VIII, Cap. 8, p. 444, Ed. cited p. 624, *supra.*

Avicenna taught that, although the narcotics were sometimes necessary to relieve tenesmus or secure sleep, their use is dangerous: they should not be administered if it can be avoided, especially to patients who are cold or whose pulse indicates debility; their use by the rectum is preferable to giving them internally, and their external application still better; he knew a patient who died from the effects of a suppository of opium.* Later physicians were long impressed with the necessity of extreme caution as to the use of anodynes in dysentery, as may be seen from the writings of Savonarola, Altomarus, Nicolaus Piso, Mercurialis, Hildanus, Sennertus and Septalius.†

But a radical change in these views was brought about by the influence of the chemical school. The reputation of the specific anodyne or laudanum of Paracelsus led to its imitation by Quercetanus, Oswald Croll, Angelus Sala and other chemists, so that numerous laudanums, all rich in opium, soon came into common use in the treatment of painful affections, among others dysentery. Angelus Sala, especially, extolled their virtues in dysentery and other alvine fluxes, and sketched a plan of treatment, in which the early use of evacuants should be followed by subsequent reliance upon the preparations of opium, which closely resembles the method pursued by Sydenham.‡ A few years later we find Riverius declaring that narcotics administered by the mouth do wonders in dysentery; that they relieve pain, check the flux, produce sleep and thus strengthen the patient. Bontius

---

* AVICENNA—Lib. III, Fen 16, Tract. 1, Cap. 4, p. 817, Ed. cited p. 632, *supra*—advised that the narcotics when administered internally should be combined with such stimulating drugs as castor, croeus and the like. His story of the unfortunate, mentioned in the text, is graphically told: "Et jam testati sumus nos vidisse, qui supposuit sibi collyrium ex opio, et mortuus fuit." After these cautions, however, he gives a number of formulæ for opium, hyoscyamus and other narcotics in combination with galls, myrrh, &c.

† MICHAEL SAVONAROLA—*Practica*, Tract. VI, Cap. 16, Rub. De dissinteria intestinali, Venetiis per Andream de Bonetis de Papia, X Maii, 1486, fol. 176 *et seq.* It has been remarked by SPRENGEL—Bd. II, S. 674, *op. cit.*, p. 346, *supra*—that he laid down very well the rules for giving opiates in dysentery, but I find him merely repeating with all docility the precautions insisted upon by AVICENNA and ALEXANDER OF TRALLES, especially the former. ALTOMARUS—*loc. cit.*, p. 689, *supra:* "Quapropter medicamenta quæ ex opio, altercо, nigro papavere, aut mandragora componuntur, vitari omnino debent, nisi forte maxime urgeat necessitas, ex Tralliani sententia," &c. NICOLAUS PISO—p. 277, *op. cit.*, p. 665, *supra*—repeats this language almost word for word. MERCURIALIS—*De Cog. et Cur. Hum. Corp. Affect.;* I cite the Venice Ed. of 1627, p. 380—remarked that stupefying remedies may be given if immoderate pain or wakefulness makes them necessary, but moderately, "quia sunt naturæ nostræ inimica." Equal caution with regard to the use of opium and other anodynes is observed by HILDANUS—Cap. 9, p. 684 *et seq.*, *op. cit*, p. 644, *supra;* SENNERTUS—T. III, p. 176, *op. cit.*, p. 645, *supra;* and SEPTALIUS—Lib. VII, § 100–101, p. 229, *op. cit.*, p. 680, *supra.* Yet SENNERTUS, notwithstanding his earnest cautions against the abuse of these remedies, admitted that opiates rightly administered are of great service, not merely relieving pain and producing sleep, but checking the flux—p. 175.

‡ I suppose PARACELSUS was not very nice in the use of his word *laudanum*, and that at various times he bestowed it upon very different nostrums. I have already referred to one of these—see note ††, p. 689, *supra*—of which antimony appears to have been the chief ingredient; and according to SPRENGEL—Bd. III, S. 500, *op. cit.*, p. 346, *supra*—that zealous disciple of PARACELSUS, ADAM VON BODENSTEIN, claimed that his more famous laudanum was not an opiate but the quintessence of mercury. But according to ANGELUS SALA—*Opiologia*, The Hague, 1614, Cap. 8, p. 33—PARACELSUS appears in a general way to have called any anodyne or comforting medicine laudanum, and the same writer bestowed the name *laudanum of Paracelsus* upon the "specific anodyne" described in his *Archidoxorum*, Lib. VII, T. II, p. 26, *op. cit.*, p. 336, *supra*, which was made by digesting Theban opium with the juice of citrons and pomegranates, cloves and cinnamon, and afterwards adding musk, saffron, &c. Various other laudanums were devised by subsequent chemists. QUERCETANUS—*Pharm. Dogmat. Restitut.*, (1603,) p. 218, Ed. cited p. 729, *supra*—modestly called his preparation *laudanum præstantissimum*, and among its uses declared that it was advantageous "contra omnes defluxiones et fluores ventris, dysentericos, hepaticos, lientericos, et similes." OSWALD CROLL—*Basilica Chymica*, (1609;) I cite the Geneva Ed., 1643, p. 199—used hyoscyamus as well as opium in the preparation of his laudanum, which he called the *laudanum Paracelsi laudatissimum*, but whether PARACELSUS had anything to do with its composition seems doubtful. He described also an *electuarium laudani*, which contained extract of mandrake as well as hyoscyamus and opium—p. 210. Among other uses of these preparations CROLL declared them beneficial "in omnibus profluviis intestinorum sive ratione humorum peccantium et mordentium, sive ratione humorum purgantium." ANGELUS SALA—p. 37, *op. cit.*—called his laudanum *nepenthes aurea:* it contained no hyoscyamus. Both he—p. 33—and HARTMANN in a note to the work of CROLL—p. 202—testify that almost every chemist had by this time a laudanum of his own; and the latter adds that for the most part all these preparations are imitated with trifling modifications from the specific anodyne of PARACELSUS, who himself had besides this anodyne another laudanum, which was metallic, being made out of gold, and the composition of which remains unknown. Among the uses of the laudanums enumerated by SALA—Cap. 9, p. 43, *op. cit.*, *supra*—was "to arrest in a natural way hæmorrhages, the dysenteric flux, menorrhagia, as also diarrhœas and alvine fluxes proceeding from great intemperance of the internal heat or any acrid and irritating humor." Further on—p. 50—he adds that in dysenteries and severe fluxes without blood, the peccant matter should be evacuated with rhubarb or other suitable remedies, and then laudanum should be given with syrup of quinces as often as is necessary. As to the derivation of the word laudanum there has been much difference of opinion, and when we consider in how many cases the mingled ignorance and audacity of PARACELSUS led him to make new words by mispronouncing or misspelling old ones, (*vide* SPRENGEL—Bd. III, S. 448, *op. cit.*—who instances, among other examples, the use by PARACELSUS of *pagoyus* for *paganus*, of *undimia* for *œdema*, &c.,) we shall not feel very sure of any of the derivations which have been given. The older admirers of PARACELSUS derived the word from *laus*, praise, or supposed it to be an abreviation of "*laudatum opiatum.*" In the index of words peculiar to PARACELSUS appended to the edition I cite—T. III, Appendix, p. 16—I read: "Laudanum Theophrasti Paracelsi, est medicina laude digna," &c. OSWALD CROLL—p. 211—explained it by the remark: "Laudabile medicamentum, quod plane suo nomini responderit, si laudanum dicas." Even according to these friendly views the term is a barbarism quite as much as if it be merely a distortion of the name ladanum, and intended to indicate that the nostrum on which it was bestowed partook of the virtues which, since the time of GALEN, (vide *De simp. med. temp. ac fac.*, Lib. VII, Cap. 10, § 28, Ed. Kühn, XII, p. 28,) have been attributed to that plant. It has also been suggested that the word is a barbarous fusion of the French article *le* with the word *anodyna*, as though the attempt were imperfectly made to say *l'anodyna;* and the antagonists of the chemists insisted that it signified *lauda non*, because it deserved no praise. Authorities for these derivations are given by MANGETUS—*Bibl. Pharm.-Med.*, Lib. XIV, T. II, Geneva, 1704, p. 591—from the *Opiologia* of WEDEL: see note §, next page

about the same time wrote of opium as indispensable in the dysentery of hot climates, and Rolfincius, a little later, bestowed the title of sacred anchor on the solid laudanum which he prescribed in two-grain doses to relieve tormina and tenesmus.* During the London dysentery of 1671 Willis gave his patients a full dose of liquid laudanum every evening, in some cases repeated it during the day, and affirmed that he had never known this practice to prove hurtful.† Sydenham used in like manner a liquid laudanum of his own device; after having bled and purged he administered a cathartic, which he followed by sixteen to eighteen drops of this preparation, and afterwards gave it in daily draughts. It was in connection with the account of this method that he wrote his well-known eulogy of opium as the chiefest gift of the Creator to the suffering human race.‡

From the time of Sydenham to the present day many physicians of reputation have relied upon this drug as the most important medicine in the treatment of dysentery. Wedel thought that genuine dysentery could not be conveniently cured without it; Ettmüller, that it is difficult if not impossible to cure the graver forms of the disease without its aid; Brunner spoke of it as a divine remedy, and Ramazzini expressed the opinion that there is no disorder in which opiates can be given more safely or in larger doses.§ It would be easy, if worth while, to add to the list of those enumerated in the work of Tralles‖ (1760)

* RIVERIUS—Lib. X, Cap. 6, p. 305, *op. cit.*, p. 689, *supra*—thought narcotics most useful when combined with astringents and corroborants. In his *Observationes*, Cent. II, Obs. 84, p. 510, *op. cit.*, he relates that he cured his own wife, who had been attacked by the dysentery prevailing in 1642, with a couple of two-grain doses of laudanum (see last note) followed a few days later by a laxative of myrobalans and rhubarb. BONTIUS—Lib. I, Cap. 4, p. 6, *op. cit.*, p. 681, *supra*—wrote: "Hoc saltem dico, si nobis hic de opio; ac opiatis non esset prospectum, frustra in calidissimis his regionibus medicinam faceremus, dysenteriæ," &c.; and he suggests that Mithridate theriaca and Philonium owe their virtues merely to the opium they contain. In Lib. III, Cap. 3, p. 65, he extravagantly lauds the extractum croci in dysentery, a preparation which he states in the following chapter—p. 67—is composed of equal parts of the choicest opium, dragon's blood, gum benzoin and oriental crocus (saffron) mixed with a third part of ambergris, (ambræ Japonicæ seu nigræ.) Of this he says: "Putoque verissimum hujus morbi, sæpe etiam venenati, antidoton esse." ROLFINCIUS—Lib. III, Cap. 17, p. 399, *op. cit.*, p. 681, *supra:* "Sacra anchora est laudanum opiatum ad gr. ij. sumtum." I know not which of the solid laudanums it was he gave.

† WILLIS—Sect. III, Cap. 3, p. 79, *op. cit.*, p. 680, *supra*—in various other passages of this chapter mentions laudanum liquidum and laudanum liquidum cydoneatum, (*i. e.*, prepared with quinces,) so that I suppose him to mean liquid laudanum in that referred to in the text, although he only says "laudani dosin satis magnam." Formulæ for several varieties of liquid laudanum, as well as the preparation with quinces and Sydenham's laudanum (see next note) are given by QUINCY—Part II, p. 16 *et seq.*, *op. cit.*, p. 731, *supra*.

‡ SYDENHAM—Sect. IV, Chap. 3, Vol. I, p. 170, Transl. cited p. 407, *supra*—explained that he followed the cathartic by his liquid laudanum, because "it is clear that even the mildest laxative, mere ecoprotic medicines, increase the cramps of the belly, and cause both dejection of spirits and general disorders to the patient." If the disease did not yield, he gave it "every day, night and morning, until recovery; nay, frequently to make things doubly sure, I give it every eight hours, i. e. three times in the twenty-four; and that in a dose as large as five-and-twenty drops—provided that the previous doses have been insufficient." The following is the formula for this preparation: "Sherry wine, Oij; opium, ℥ij; saffron, ℥j; cinnamon in powder, cloves in powder, āā ℥j. Mix, and put into a vapour-bath, for two or three days, until the liquor become of a proper consistency. Strain, and lay by for use," p. 173. It was after giving this receipt that SYDENHAM wrote the eulogy of opium beginning, "And here I cannot but break out in praise of the great God, the Giver of all good things, who hath granted to the human race, as a comfort in their afflictions, no medicine of the value of opium, either in regard to the number of diseases that it can control, or its efficiency in extirpating them."

§ G. W. WEDEL—*Opiologia*, Jena, 1674. Our library does not yet possess a copy of this learned work, and I cite from the reprint of MANGETUS—T. II, p. 514, *op. cit.*, last page: "Sine opio nullam veram dysenteriam curari commode posse." He adds: "Bone Deus! vidimus in dysenteria, statim in principio 40, 50, 60 intra ♂ ♀, (incredibile dictu) ægros fuisse macerates, dejectosque sedibus. Dato convenienter opio, statim pacatiori rivo mali sentina effluxit." MICHAEL ETTMÜLLER—*Diss. de virtute opii diaphoretica*, (1679,) Cap. 1, § 4, Diss. Academ., p. 186, Opera, Lyons, 1690: "Dysenteriæ graviori absque opio succurrere difficile, ne dicam impossibile est." See also *De Morb. Hum. Corporis in Genere*, Cap. IX, p. 126, *op. cit.*—where he cites the experience of RIVERIUS and others, and exclaims, "Unde etiam tot præstant exempla feliciter curatarum dysentariarum per *sola opiata;*" yet adds that he does not advise them to be given alone in the beginning of the disease, but combined with sudorifics or even if necessary with gentle abstergents, such as rhubarb. Among the preparations of opium he praises the diascordium of FRACASTORIUS—see his *De contagionibus et contagiosis morbis*, (1546,) Lib. III, Cap. 7, fol. 142, Opera, Venice, 1555—a mixture of opium with scordium, (water germander,) whence its name, dittany, tormentil, bistort, galbanum, styrax, gentian, cinnamon, cassia, piper longus, ginger, Armenian bole, terra sigillata, &c. It was used in dysentery not merely by ETTMÜLLER and many of his predecessors, but after his time, especially on the Continent almost to the present day. The propriety of using it is gravely discussed by SAVIGNAC, who declares that it is neither better nor worse than theriaca. It will be found with but little modification in the French Codex of 1866, p. 502. J. CONRAD BRUNNER—*Experimentum in dysenteria*, Ephem. German., Dec. II, an. 6, 1687, Obs. 195, p. 391: "Incassum tamen laboratur, nisi opiata succenturientur, remedia plane divina in hoc morbo." B. RAMAZZINI—*De constitutionibus annorum* 1692, 1693 *et* 1694, § 33, Opera, London, 1717, p. 113: "Dysenteriis porro, quas anno 1693 per autumnum peticulari febri supervenisse superius dixi, egregie contulisse opiatorum usum observavi; nec forsan ulla est affectio in qua securius, et liberaliori dosi exhiberi possit hoc remedii genus, quam in hujusmodi morbo, fractis licet, ac pene attritis viribus."

‖ B. L. TRALLES—*Usus Opii Salubris et Noxius in Morborum Medela*, Sect. III, Breslau, 1760, p. 172 *et seq.* Among the advocates of opium in dysentery referred to in this learned work that I have not been able to consult, I may mention J. J. WEPFER—*Diss. de dysenteria præcipue maligna quæ per æstatem et auctumnum* 1712 *in Cleria et vicinis regionibus grassata est*, Duisburg, 1703—who claimed to have cured six hundred cases with laudanum alone. To the authorities cited by TRALLES I will here only add CLEGHORN—Chap. 5, p. 254, *op. cit.*, p. 637, *supra*—who, after the administration of evacuants in the early stages of dysentery, found it "absolutely necessary to give opium twice a day, in order to obtain some respite from perpetual torment, and gradually to increase the dose, from half a grain to five or six, as use made it familiar." This was his main reliance, but "once or twice a week or oftener, as the strength would allow," he used also clysters, cathartics or small doses of ipecacuanha "to hinder the acrid matter from being accumulated in the intestines." He adds: "If by these means the patient can be kept alive during the first severe winter weather, he stands a good chance of holding out to the summer, which commonly restores him to his former health, when he must be weaned by degrees from the use of opium; from the continuance of which medicine, in such cases, I have never found any ill effects ensue."

as having placed their principal reliance upon its virtues; and many later physicians have rivalled their predecessors in extravagant praise.

Van Geuns administered opiates boldly during the Harlingen epidemic, regarded them as possessed of wonderful powers in resisting the tendency to gangrene, and cites a letter from Voltelen, who gave as much as twenty-four grains of opium in the twenty-four hours.* Vogler declared that opium is the best of all the measures devised against dysentery; he held that it should be administered freely, and as early in the disease as possible; out of more than a hundred patients thus treated during the Weilburg epidemic of 1791 not one died.† Richter, who had the opportunity to observe three considerable epidemics in the vicinity of Gottingen, also relied upon opium as the most important medicament.‡ Rademacher trusted chiefly to laudanum during the Cleves epidemics; he gave to one patient, a woman, twenty-five drops four times daily for three weeks.§ Chapman declared that without the aid of opium he should not know how to proceed in the treatment of dysentery.‖ Christison gave it in two- or three-grain doses during the Edinburgh epidemic of 1828, and asserted that in urgent cases it was sometimes necessary to give as much as twenty-four grains of opium in twenty-four hours.¶ Paterson advised that the treatment of dysentery should be commenced by the administration of a drachm and a half or two drachms of laudanum, and that subsequently six grains of powdered opium, with three of calomel and half a grain of tartar emetic, should be given every eight hours.** Bamberger taught that of all the medicines used internally in the treatment of dysentery, opium was that from which the most was to be expected in severe cases.††

The latest utterance of this kind comes from that skilful practitioner Austin Flint, who holds that our chief reliance, particularly in epidemic dysentery, should be placed upon opium; and in emphasizing the tolerance of this drug, sometimes observed, relates that he gave to one patient suffering with this form of the disease no less than twenty-four grains

* VAN GEUNS—S. 29 *et seq.*, *op. cit.*, p. 649, *supra*—in the Harlingen epidemic gave an emetic of ipecacuanha, with or without tartar emetic, and followed its operation with opiates. In severe cases he gave as much as 40 to 60 drops or more of liquid laudanum—S. 54—or 8 to 12 grains of solid laudanum—S. 61. So far was he from admitting that opium produced a tendency to gangrene, *(vide infra,)* he held that it acted in a wonderful manner in preventing this dreaded complication—S. 57. He quotes with approval a letter from HOFF, who wrote that "opium is the great medicine, but it must be given in sufficient doses; small doses are of no avail"—S. 60; and a letter from F. J. VOLTELEN, who advocated the use of solid opium, and while taking credit to himself for not giving such large doses as STINSTRA and LENZIUS, admitted that he once gave 24 grains in the 24 hours. I note that according to HAUFF—S. 406, *op. cit.*, p. 534, *supra*—VAN GEUNS himself gave as much as a drachm of opium daily, which appears to be a misunderstanding; I suppose a case to be referred to—S. 86—in which he gave a drachm of liquid laudanum daily for eight days.

† J. P. VOGLER—*Von der Ruhr und ihrer Heilart*, Giessen, 1797, Kap. 7, S. 158 *et seq.* The statement with regard to the Weilburg epidemic will be found on S. 173; but he admitted that opiates are sometimes contraindicated, (see Kap. 8, S. 203 *et seq.*,) and held that it should not be given in excessive doses, or too long continued. The dose of solid opium or its extract should not exceed two-thirds of a grain—S. 198. This work appears to have exercised considerable influence in extending the employment of opium in dysentery among subsequent German practitioners.

‡ RICHTER—S. 86 *et seq.*, *op. cit.*, p. 731, *supra*—stated that he believed with AKENSIDE, STOLL and VOGLER, that dysentery does not depend upon bilious, corrupt accumulations in the intestinal canal, but that it is a catarrhal or rheumatic affection of the intestine; and he held that it cannot be cured by purgatives or emetics, but that the proper remedies are sedatives (reitzstillende Mittel) and diaphoretics. He, indeed, gave emetics, and combined antimony with opium as a diaphoretic, but he declared "Mohnsaft war das Hauptmittel," and added with ingenious sophistry: "Schmerzen sind beynahe das einzige Symptom der Krankheit; schmerzlindern das einzige Geschäfte des Arztes. Tormina nennten die Alten die Krankheit," S. 101.

§ RADEMACHER—p. 79 *et seq.*, *op. cit.*, p. 734, *supra*. The years referred to in this treatise are especially 1795, 1796, 1800 and 1802. The case mentioned in the text occurred during the first of these years; it is related in a communication to Hufeland's Journal, Bd. II, 1796, S. 600: see also, in the same Journal, Bd. IV, 1797, S. 554, an essay by the same author, *"Ueber die Ruhr, welche im Jahre* 1796 *zu Cleve herrschte."*

‖ N. CHAPMAN—*Elements of Therapeutics and Materia Medica*, Vol. II, Philadelphia, 1819, p. 208: "Even by Cullen the use of opium in dysentery is condemned, and he is not alone in this respect, though surely he is wrong, or there is a strange delusion on the subject. Consulting my experience, I must say, that in dysentery opium cannot be dispensed with. Deprived of its aid, I should really not know how to proceed in the treatment of the disease:" see also subsequent editions, including the 4th Ed., Philadelphia, 1825, Vol. II, p. 179.

¶ ROBERT CHRISTISON—*Notice on the dysentery which has been lately prevalent in the Edinburgh infirmary*, Edin. Med. and Surg. Jour., Vol. XXXI, 1829, p. 216—summed up his treatment by remarking that it "consisted at the commencement in the liberal use of opium, preceded in some instances by the free application of leeches to the lower part of the belly, and frequently accompanied with the application of large blisters, and with the use of the warm-bath:" see also the same author, *On the employment of opium for arresting acute internal inflammations*, London and Edinburgh Monthly Journal of Med. Sci., Vol. I, 1841, p. 92.

** A. PATERSON—*Obs. on the pathology and treatment of dysentery*, Lond. Med. Gazette, Vol. XIII, 1834, p. 200—remarks: "By this simple plan, and with no addition except what the urgency of any particular symptom demanded, I have been enabled to cure every case of dysentery that has come under my care in a much shorter period, and with greater ease to the patient, than could have possibly been the case if either the mercurial or the cathartic mode of treatment had been followed."

†† BAMBERGER—S. 410 u. 417, *op. cit.*, p. 578, *supra*.

of the sulphate of morphia in the twenty-four hours, for several days; a quantity which throws the older observations just cited quite into the shade.*

But these extravagant views encountered equally extravagant opposition from the very first. As early as the beginning of the seventeenth century Minadous observed foul ulcers in the intestines of patients dead of dysentery after the fruitless use of opium, and expressed the opinion that the retention of acrid humors produced by the drug had caused them to become more putrid than they would otherwise have been. This view was advocated by Thoner, (1651,) whose aphorism, "Narcotica in dysenteria esse necrotica," was long accepted in many quarters.† Frid. Hoffmann adopted it at least for the beginning of the disease, during which, he taught, the stronger opiates and astringents should be carefully avoided lest the inflammation be converted into a fatal sphacelus. To restrain the excessive intestinal motion or spasm he preferred milder anodynes, especially his own anodyne liquor, and rather than advise opium he even sanctioned with his authority the use of various ridiculous animal substances, which the superstition of former ages had introduced into the treatment of dysentery and endowed with imaginary anodyne virtues.‡

To these earlier protests must be added the prudent warnings of many later physicians, especially those who have had the opportunity to study epidemics of severe dysentery. Degner§ held that the use of narcotics and opiates should be regarded with suspicion, affirmed that observation showed their use too early in the disease, or in too large doses, to produce doubtful or even fatal results, and thought them apt to lull both patient and physician into a false security: only after the free use of evacuants did he prescribe mild anodynes, and then with the greatest caution. Very similar were the opinions maintained by Young, Pringle, Tissot, Eller, Baker and Zimmermann.‖ They all regarded the employ-

---

* AUSTIN FLINT—*op. cit.*, note ‡, p. 703, *supra*—strongly commends opiates in certain sporadic cases also in this lecture. With regard to epidemic dysentery he says: "So far as medical treatment is concerned, our chief reliance must be placed upon opium. Administer opium early and persistently, and to the extent of absolutely quieting the intestines, but at the same time avoiding the risk of narcotism." He adds, "that, in certain cases at least, there is a wonderfully increased tolerance of opium. For example, I have given a patient, suffering from epidemic dysentery, a grain of the sulphate of morphia every hour—24 grs. per diem—and continued such doses for several days without producing the least manifestation of narcotism; and the patient was a person not accustomed to taking opium. That was an extraordinary case, it is true, but I have been repeatedly led to observe a greatly increased tolerance of opium in this class of cases." This commendation of such dangerous practice by a physician whose opinions are deservedly so much esteemed, makes it a duty to point out that, of twenty-six cases enumerated by him in his *Clinical report on dysentery* (cited p. 710, *supra*) as treated chiefly or exclusively by opium and its preparations, six died, while of ten cases which the same author permitted to run their course without treatment—see note *, p. 349, *supra*—all terminated in recovery. It may be reasonably objected that this application of the "statistical method" is hardly fair in the absence of definite information as to the relative severity of the two groups of cases, but this criticism will also apply to the method employed by our author in his "clinical report," and to all the deductions it contains. I may add that of 23 other cases enumerated in this report as having been treated chiefly with calomel and opium, five died.

† JOHN THOMAS MINADOUS, according to MANGETUS—T. II, Pars 1, p. 338, *op. cit.*, p. 710, *supra*—was appointed professor in Padua in 1596, and died in 1615. MANGETUS gives a list of his writings, none of which I have seen. I take the statement in the text from A. THONER—*Obs. Med.*, Ulm, 1651, Lib. III, Obs. 8, p. 167. In this observation, headed "Narcotica in dysenteria esse Necrotica illustri exemplo ostenditur," after relating the case of a certain count who took opium (aliquot granis laudani opiati) for dysentery, became stertorous, and died, he adds: "Exin Thomas Minadous, Medicus et Professor Italus, se observasse asserit, omnes dysentericos, quibus ex consilio Medicorum laudanum opiatum oblatum, defunctos: post eorum usum, ulcera magis putrida et sordidiora reddita, ex longiori mora materiæ purulentæ, et acriorum humorum." We have the testimony of B. L. TRALLES—Sect. III, p. 177, *op. cit.*, p. 737, *supra*—that these views were shared by many subsequent physicians, (recentiorum sat multi.) See also the references to HOFFMANN and DEGNER, *infra*.

‡ HOFFMANN—T. III, p. 155, *op. cit.*, p. 681, *supra*—admitted, as his second indication for the treatment of dysentery, to soothe tormina and spasms of the intestines. This, he says, should be done with the "safer anodynes and milder subastringents." He says that theriaca, aqua theriacalis, diascordium, pills of cynoglossus, (which contained opium,) the liquid laudanum of Sydenham, &c., are commonly used, but it is far safer to give his anodyne liquor mixed with moderate doses of his balsam of life. In the cautelæ et monita appended to this chapter, § 1, p. 157, he expressly asserts that the stronger opiates (crassa opiata) and astringents, if given in the beginning of the disease, cause the retention of the caustic humors, and if the strength of the patient is broken, readily act as "necrotica," and convert the inflammation into fatal sphacelus. In § 2 he commends the safe anodyne virtues of the spines and livers of vipers, scrapings of the teeth of the hippopotamus, the bones of the sea-cow, the penis of the whale and dried human secundines.

§ DEGNER—Cap. III, § 70, p. 180 *et seq.*, *op. cit.*, p. 625, *supra*. Among the anodynes, he mentions pills of cynoglossus, syrup of white poppies, diascordium and theriaca; but he adds that even the syrup of poppies and theriaca are not sufficiently safe, and in a foot note—p. 184—says of soporific remedies: "Hinc antiquis æque ac recentioribus medicis semper suspecta fuerunt, qui jam diu clamarunt: in hoc morbo narcotica esse necrotica."

‖ GEORGE YOUNG—*A Treatise on Opium*, London, 1753, Sect. VII, p. 47 *et seq.*—wrote: "For my own part, when I reflect how commonly opium is used in this disease, without any caution, I suspect its effects are too often fatal." He held that in plethoric patients, if the stools are fetid, viscid and scanty, opium will certainly increase the disorder, and remarked: "I use opium only when the disease is mild, or after its violence is abated by evacuants and emollients." If the dysentery be attended with a fever, he thought opiates still more prejudicial. Sometimes, however, he combined opiates and purgatives with advantage. The same physician, in his account of cerated glass of antimony, published by PRINGLE—p. 199, *op. cit.*, p. 690, *supra*—wrote: "I never chuse to give opiats in the beginning, especially where there is great sickness; because although opium gives great relief to some, yet

ment of opiates at the beginning of the disease as dangerous, and counseled caution as to their use in the more advanced stages. Pringle felt so strongly on the subject that he emphatically declared it were better opiates were never used at all than given before the first passages were thoroughly cleansed.

Cullen maintained that opium is at best a precarious remedy in dysentery, to be avoided as much as possible.* Hufeland cautioned against using it, especially in the bilious forms of the disease, in which he thought there was the greatest danger to be apprehended from the suppression of the discharges.† Twining held the idea of curing the serious lesions of grave dysentery by the use of opium in great contempt, and affirmed that he had seen it prove exceedingly injurious by masking the deadly symptoms until the patient was past recovery.‡ Berndt, who treated numerous cases of mild dysentery with opium in his early practice, states that, although many of them recovered, many others were certainly injured by this mode of treatment.§ Canstatt, while he admitted the power of opium in temporarily relieving the painful symptoms of dysentery, thought that it is so apt to do mischief, by causing the retention of acrid matters in the intestinal canal and increasing the tendency to adynamia, that it is best to use it very sparingly.‖ Trousseau only mentioned opium, in connection with dysentery, in order to raise his voice against the deplorable abuse of the remedy too often witnessed.¶ Savignac believed that opium ought not to dominate in the treatment of dysentery, but should be confined to the modest role

at other times I have thought both the sickness and purging thereby increased the following day." PRINGLE—p. 282, 1st Ed., 1752, cited p. 693, *supra*—gives as a reason, "For, tho' they afford some ease; yet, by penning up the wind and corrupted humours, they fix the cause." He refers to the opinion of SYDENHAM, and remarks: "But, whatever was the nature of those fluxes, I am well assured, that these incident to an army are of a less gentle nature, and never to be cured without evacuations. The best rule, therefore, is to withhold opium till the patient is both vomited and purged; and when it becomes necessary, to begin with small doses." These views are repeated on pp. 263–4 of his 7th Ed., 1774, cited p. 640, *supra*. In this edition will also be found—p. 268—an observation which appears already in the 4th Ed., 1764, p. 277: "After clearing the first passages, in the manner described above, I have generally endeavoured to finish the cure, by combining purges with opiates, in such a manner as to keep the body open, and at the same time to appease the gripes: but I have not always succeeded to my wish." TISSOT—T. III, p. 18, *op. cit.*, p. 625, *supra*—speaks of the plan of trying to check the discharges in dysentery by opium and astringents as "méthode mortelle." J. T. ELLER—*Obs. de Cog. et Cur. Morbis præsertim Acutis*, Leipsic, 1762, Sect. XIII, De dysenteriis, et in specie de dysenteria epidemica, p. 273—held that the relief of pain afforded by the use of opiates was brief, that it debilitated the tone of the intestinal fibres, and actually made the disease worse. BAKER—p. 31 *et seq.*, *op. cit.*, p. 437, *supra*—thought that it was dangerous to give opiates before the stools reacquired the fæcal character, and that until then they should be administered sparingly or not at all. ZIMMERMANN—Cap. V, S. 96, *op. cit.*, p. 648, *supra*—always looked upon it as dangerous to give opium in dysentery before the acrid humors were got rid of, (eh der Zunder des Uebels zernichtet ist.) After their thorough evacuation he sometimes obtained benefit from liquid laudanum; but without rhubarb, given at intervals between the doses, or just after them, it was evidently injurious—S. 99. In Cap. 10, S. 413 *et seq.*, he recites the opinions of DEGNER, PRINGLE, BAKER and others who have cautioned against the early use of opium, and remarks: "All these prudential rules agree with those which my own experience has taught me"—S. 418. I may mention here the dissertation of D. G. BRÜNING—*Ueber die Schädlichkeit des Mohnsaftes in der Ruhr*, Gera, 1794—which I regret that I have not been able to see, as it is frequently quoted by subsequent writers.

* CULLEN—*A Treatise of the Materia Medica*, Edinburgh, 1789, Vol. II, p. 244: "If I am right in the pathology I have elsewhere endeavoured to establish, it will be obvious, that if the present practice of the frequent use of gentle laxatives be the most effectual measure, it will be equally evident that opiates must be commonly hurtful; and notwithstanding the urgency of pain, it is at best a very precarious remedy, and to be avoided as much as possible." In his *First Lines*, § 1083, Vol. II, p. 325, Ed. cited p. 648, *supra*, he admits that opiates "are very effectual for the purpose of relieving from the gripes;" but adds: "I believe it indeed to be only the neglect of purging that renders the use of opiates very necessary."

† HUFELAND—*Bemerk. uber die im Herbst* 1795 *in und bey Jena ausgebrochne Ruhrepidemie*, Hufeland's Jour., Bd. I, St. I, 1795, S. 76 *et seq.*—recognized a simple or rheumatic dysentery, a gastric or bilious dysentery, a form characterized by inflammatory complications, and one in which putrid complications occurred. Opium, he held, increases the force of the pulse, the turgescence of the blood and the temperature—S. 126. He, therefore, preferred extract of nux vomica, which he used also as a narcotic, except when the perspiration was suppressed, when opium may be used on account of its diaphoretic virtues; but either remedy, if given in bilious dysentery—S. 135—may produce dangerous consequences by checking the discharges and giving rise to what he called "gestopfte Ruhr;" it is even possible by large doses of narcotics to paralyze the intestinal canal—S. 136.

‡ TWINING—Vol. I, p. 72, *op. cit.*, p. 608, *supra:* "When we remember the actual condition of the local disease, which is to be removed before we can cure the severer forms of acute dysentery; we shall hold opiates in great contempt," &c. But "although opium has no direct effect in curing the acute inflammation existing in recent cases of dysentery," he thought, however, that enemata of laudanum were of great service in "procuring a temporary respite from pain and restlessness."

§ BERNDT—Hefte 3 u. 4, S. 227, *op. cit.*, p. 717, *supra:* "Ich selbst habe in früheren Zeiten das Opium als Heilmittel bei der Ruhr angewendet und manchen Kranken damit geheilt. Indessen muss ich doch der Wahrheit getreu bekennen, dass beim Gebrauch des Opiums der Regel nach eine langsame Heilung erfolgt ist, und dass ich viele Fälle beobachtet habe, wo es ganz offenbar Nachtheil gebracht hat."

‖ C. CANSTATT—Bd. I, S. 524, *op. cit.*, p. 717, *supra*. He charges opium with producing a semi-paralytic condition (Halblähmung) of the muscular coat of the intestines, thinks that the retained putrid matters may not only act locally as irritants capable of increasing the intestinal inflammation, but may be reabsorbed and increase the toxic condition of the bloodmass, (steigern die Toxicose der Säftemasse,) and thinks that on the whole the practitioner who uses it sparingly will do much better than he who employs it lavishly.

¶ TROUSSEAU—T. III, p. 170. *op. cit.*, p. 664, *supra:* "Je n'ai à vous en parler que pour m'élever contre les déplorables abus que l'on en fait encore trop souvent." If it is sometimes indicated, he says, it is only to relieve the accompanying pain, or arrest the vomiting that prevents the use of other remedies, and not to combat the dysenteric flux. So cautious was he that he advised the practitioner to commence even in these cases with a single drop of the laudanum of Sydenham every hour, and declares that if large doses be employed there is danger that grave typhoid symptoms will ensue.

of a mere adjuvant;* and Heubner disapproved of the methodical use of opium in this disease, advising that it should only be given temporarily and as a palliative remedy.†

It is not surprising that the extreme divergence of the two groups of opinions just sketched should have given rise to doubts and perplexities in many minds, or that the sentiment of the celebrated George Ernest Stahl, who was usually dogmatic enough, but who confessed that he was not prepared either to blame or to praise the use of opium,‡ should have found an echo in many minds. But notwithstanding all doubt or opposition, it has continued to be pretty freely employed in combination with other remedies even by those who did not trust it as directly curative. Indeed many of those whose objections have been cited in these pages have themselves employed it, though for the most part with commendable caution, while others have been much more liberal in its use.

Boerhaave and Van Swieten favored the plan of resorting to opium after the irritating acrimony from which dysentery originates has been expelled by emetics, purges and clysters.§ Donald Monro, although very sparing of the dose in the first stage of the disease, gave even then an opiate at night, and later in the disease administered astringents mixed with opium; in chronic dysentery he regarded its free use as indispensable.‖ Even Stoll, who laid such stress on the employment of emeto-cathartics in the early stages of dysentery, resorted to opium without hesitation in the subsequent treatment.¶ Hunter adopted a similar course.** Moseley, though he could not help expressing his concern at the continuance in army and navy practice of the custom of giving large doses of opium at night, did not hesitate to administer it, combined with his favorite diaphoretics, as he thought occasion required; observing that its real use is to arrest the hurry of the disease as well as to ease the tormina, and that when given for these purposes its matchless power is

---

* SAVIGNAC—p. 375 *et seq.*, *op. cit.*, p. 620, *supra*—cautions his readers against being misled by "marvellous recitals of cures due to the preponderating or exclusive employment of opium." Its principal use is to calm the violence of the tormina and tenesmus and to facilitate the action of other medicines, as, for example, purgatives, or, in the chronic forms of the disease, astringents.

† HEUBNER—S. 544, *op. cit.*, p. 529, *supra*—remarks, moreover, that it is impossible, with opium or morphia, to keep the bowels at rest all the time. The colic and tenesmus are moderated only for a while, and then in spite of large doses become more violent than before; besides, the state of stupefaction and heat into which the patient is brought by opium is decidedly unfavorable in dysentery.

‡ J. H. HEILERSIEG—*Diss. de dysenteria*, Halle, 1706, p. 32. This dissertation, prepared under the presidency of STAHL, confessedly represents his views. The author writes: "Opiatorum usum, ut alias non tam ex hypothesi, quam potius praxi, D. D. Præsidis, non facile, nunquam vero absolute sine summa cautione, suadendum esse putamus; ita etiam in hoc casu, non quidem damnamus, sed neque laudamus." He goes on to say that opium is unable to cure any disease, it only obtunds symptoms, and indeed not the symptoms, but only the sensation of them, and more rarely the motion accompanying them, and ends by advising that if opium be used, theriaca or pills of cynoglessus should be preferred. The ambiguous position of STAHL in this matter has been sharply criticised by WERLHOF—*Cant. med. sive diss. de limitandis morborum vituperiis et laudibus medelarum*, Tract. I, § 4, Opera Medica, Pars II, Hanover, 1775, p. 339; and TRALLES—Sect. III, p. 181, *op. cit.*, p. 737, *supra*.

§ VAN SWIETEN—§ 722, T. II, p. 393, *op. cit.*, p. 663, *supra*. The object assigned by BOERHAAVE in the aphorism here under discussion is "pacatione impetus [scl. acris irritantis] per narcotica." Elsewhere BOERHAAVE—*Consult. Med.*, Gottingen, 1752, Vol. II, Casus 6, p. 22, Responsio consultatoria circa dysenterias castrenses, imperatoris Romani exercitus devastantes—counselled that the treatment should be begun with an emetic of antimonial wine repeated daily for three days, or a daily purge (of rhubarb, myrobalans and scammony) repeated as often, followed ten hours later by two grains of opium, and after the venom was thus expelled he gave a mixture of Armenian bole, catechu, theriaca, &c.

‖ DONALD MONRO—p. 75 *et seq.*, *op. cit.*, p. 625, *supra*—also gave opiates sometimes in the daytime "between the purges," but usually only Mithridate with Mindereri draughts, or saline draughts with the addition of four drops of the tincture of Thebaica, or some such mild diaphoretic, and thought this better than to give "the Diascord, or Philonium, or other strong astringents and opiates commonly prescribed for this purpose; which were always liable to check the purging too much, and bring on severe gripes attended with heat and fever; and therefore we seldom made use of them in this first stage of the disorder." But, "after some weeks when the fever had abated," he used "corroborating and gentle astringent medicines, mixed with opiates,"—p. 79—such as the mixtura Fracastorii, repeated doses of the Philonium Londinense, the Theriac anodyne boluses, &c.—p. 82—or in other cases from three to ten grains of ipecacuanha with one of opium every four or six hours, or Dover's powder in one- or two-scruple doses—p. 84. In his later work—Vol. I, p. 349 *et seq.*—he expresses the opinion that opium had better be omitted altogether for the first twelve or fourteen days, that afterwards mild opiate and diaphoretic medicines be given in the intervals, but not to the extent of stopping the discharges, and "that in old dysenteries where the disorder has become in a manner chronic, the free use of opium is often absolutely necessary."

¶ STOLL—Cap. 2, p. 252, *op. cit.*, p. 342, *supra*—cured the simple rheumatismal dysentery of 1778 by tepid emollient drinks with powdered nutmeg and a little opium at bedtime. He formally defends SYDENHAM ("quem virum, et quantum!") from the charge of having made too much use of opium, pointing out that he did not employ that treatment in all varieties of dysentery—p. 254. In bilious dysentery (rheumatico-biliosa) STOLL gave an emetic or an emeto-cathartic, and this usually cured the disease without subsequent resort to narcotics. This form of dysentery, he thinks, it was that SYDENHAM cured with repeated purges followed by laudanum—p. 259—and he himself gave without hesitation the nepenthes of Helen (a kind of laudanum) after the action of the emeto-cathartic in these cases—p. 287. In the dysenteric bilious fever, however, he thought that opium should be given more sparingly, and later in the disease. So confident was STOLL in the efficiency of his plan of treatment that he declared that there is hardly any disease, among those which are called epidemic, so easily cured at the beginning, or that being neglected is so devastating in its effects—Cap. 7, p. 321.

** HUNTER—p. 239 *et seq.*, *op. cit.*, p. 637, *supra*—sometimes combined opiates with the purgatives, but generally preferred to use them alternately.

worthy of admiration.* Fournier and Vaidy commended the liberal employment of opium after the use of evacuants. Broussais gave it in both acute and chronic dysentery.†

Almost all the physicians who, in the latter part of the last and during the present century, have placed their main reliance on repeated doses of calomel, as well as those who have employed ipecacuanha for its diaphoretic action, or on the so-called non-emetic plan, have combined opium with these remedies, and often so freely as to give rise to the allegation that it was, after all, to the opium thus employed that the success of their medication was due.‡ In like manner those who have made free use of astringents, whether during the progress of acute dysentery or in the chronic forms of the disease, have usually conjoined opium with them, and often in considerable doses. It is not necessary to bring forward here the long list of those who have pursued these methods: the combinations with astringents will be discussed further on; those with calomel and ipecacuanha have already received sufficient attention. Let it suffice, at present, to refer to the works of Naumann, Hauff, Baly, Copland, Vogt, Morehead, G. B. Wood, Niemeyer and Barrallier,§ for illustrations of the liberal manner in which opiates have been employed in the treatment of dysentery by some of the most respected practitioners of medicine who have flourished during the last forty years. Since the discovery of morphia,‖ the salts of that alkaloid have been very frequently substituted for the other preparations of opium, and as early as the Wurtemberg epidemic of 1834 its endermic application began to attract attention.¶

At the commencement of our civil war the teachings of George B. Wood, who regarded opium as an invaluable remedy in dysentery, and combined it at almost every stage of the disease with the other medicines employed, were widely accepted by American practitioners; not a few shared the warm admiration with which Austin Flint regarded the use of the drug; while in the tract of Stillé,** although judicious prominence was given to ipecacuanha,

* MOSELEY—pp. 230, 237 and 239, *op. cit.*, p. 648, *supra*.

† FOURNIER et VAIDY—p. 380 *et seq.*, *op. cit.*, p. 362, *supra*. They regard it as very injurious, however, in the early stages of bilious dysentery—p. 396—and in dysentery complicated with typhus—p. 397. BROUSSAIS—T. III, p. 216, *op. cit.*, p. 643, *supra*—gave the laudanum of Sydenham or the syrup of opium in acute dysentery to relieve severe tenesmus and tormina, and made it the most important part of the treatment of chronic enteritis: "Les médicamens qui peuvent concourir, avec le régime, à la cure des phlegoses chroniques de la membrane muqueuse du colon, se réduisent, pour moi, à quelques stomachiques et aux anodyns"—p. 224. But he prescribed them with a sparing hand at first, not exceeding twelve drops of Sydenham's laudanum, or half a grain of opium, given at night; afterwards, if necessary, increasing the dose to 50 or 60 drops of the laudanum.

‡ For example, see the comments of BAMBERGER with regard to the diaphoretic use of ipecacuanha, referred to on p. 694, *supra*.

§ NAUMANN—Bd. IV, Abth. 2, S. 85 *et seq.*, *op. cit.*, p. 645, *supra;* HAUFF—S. 404 *et seq.*, *op. cit.*, p. 534, *supra;* BALY—p. 535, *op. cit.*, p. 535, *supra;* COPLAND—Vol. I, p. 728, *op. cit.*, p. 682, *supra;* VOGT—S. 183, *op. cit.*, p. 645, *supra;* MOREHEAD—p. 302, *op. cit.*, p. 657, *supra;* G. B. WOOD—Vol. I, p. 721, *op. cit.*, p. 671, *supra;* NIEMEYER—Bd. II, S. 755, *op. cit.*, p. 645, *supra;* and BARRALLIER—p. 771, *op. cit.*, p. 603, *supra*. In striking contrast to the reserve with which the use of opium was regarded by HEUBNER—see note †, p. 741, *supra*—is the freedom with which it was prescribed by FRANZ SEITZ—No. 7, 1872, S. 84, *op. cit.*, p. 651, *supra*—who combined it with the demulcent or albuminous drinks, on which he placed his main reliance in the early stages of the disease, as well as with the astringents he gave at a later period. I note that SEITZ was so cautious with regard to the use of laxatives in dysentery that he only recommended them in cases in which the fæcal accumulation can be recognized by palpation and percussion.

‖ By SERTÜRNER, 1816—see the *Pharmacographia*, p. 53 *et seq.*, Ed. cited p. 704, *supra*—who called it morphium.

¶ HAUFF—S. 408, *op. cit.*, p. 534, *supra*—remarks that opium has been used "neuerdings auch als Morphium, welches man auch endermisch anzuwenden versucht hat (Rampold)."

** WOOD—*loc. cit.*, note §, *supra;* AUSTIN FLINT—note *, p. 749, *supra;* STILLÉ—*op. cit.*, p. 650, *supra*—in the treatment of "mild dysentery," advises, after a cathartic of calomel followed by castor oil, "a small opiate draught," or from 5 to 10 grains of Dover's powder, "to promote rather than to enforce sleep, to allay tenesmus, and moderate the frequency of the stools." If the disease continues, he gives "purges every second day, and the mild opiates at night, until the tormina and tenesmus have ceased, or nearly so," and then pills of acetate of lead or nitrate of silver with ⅛th of a grain of opium every four or six hours—p. 362. In "sthenic or inflammatory dysentery" he advises the administration of 3 to 5 grains of Dover's powder, every three hours, between the "courses" of saline laxatives he commends for robust patients—p. 364; or when calomel is given, that a grain of opium be combined with each dose, and subsequently "the remainder of the medical treatment may in general be confined to five-grain doses of Dover's powder every five or six hours, or from three to five grains of ipecacuanha, with half a grain or a grain of opium at like intervals"—p. 365. Enemata of laudanum are commended in this form of the disease on p. 366, and acetate of lead and opium pills on p. 367. In "bilious dysentery," the premature exhibition of opiates is to be sedulously avoided; "but when once bilious evacuations have been procured, the administration of small doses of wine of opium or of Dover's powder may be cautiously resorted to for allaying pain and lessening the discharges"—p. 371. In "malignant or typhoid dysentery," although opium should be given with caution, yet it is perhaps the only medicinal substance, besides nitrate of silver, which is appropriate for internal use—p. 375. In "periodical dysentery" opiates are to be combined with quinia—p. 377; and in "chronic dysentery" with the mineral astringents—p. 378. In his *Therapeutics*, Vol. I, p. 870, Ed. cited p. 711, *supra*, our author writes: "In mild attacks of dysentery there is no doubt that opium alone, or that purging alone, will effect a cure, but it is equally certain that rest, diet, diluent drinks, and emollient clysters will have the same effect; but, when the disease is severe, no exclusive plan can be relied upon, and least of all, perhaps, that by opium." Nevertheless, after the violence of the malady has been broken by emetics, laxatives or diaphoretics, he thinks that opium should be employed, alternating with them, or following them, for the purpose of "perfecting the cure," and he holds that "chronic dysentery is materially benefited by opiates."

the neutral salts and other evacuants, opiates were commended, for the most part however in moderate doses, in every form of the disease.

Tripler, instructed by a military service of over thirty years, which included the arduous Mexican campaigns, was far more careful in this direction. He not merely regarded opiates as well as astringents as worse than useless at the beginning of the treatment, but prescribed them in the subsequent stages in the most sparing manner, and even went so far as to throw doubts on the usefulness of anodyne enemata.* On account of his prominent position as Medical Director of the Army of the Potomac, his views became generally known and secured a considerable number of followers; but it is safe to say that the partisans of opium were very much in the majority. Those who began the treatment with saline cathartics or other evacuants very often followed their operation by full doses of opium. Indeed some laudanum or other opiate was frequently added to the first cathartics administered. Those who gave repeated doses of calomel, blue pill or mercury with chalk, whether with or without ipecacuanha, almost invariably added some preparation of opium to the pills or powders. The vegetable or mineral astringents, employed during the later stages of acute dysentery, as well as the mineral acids which some preferred, were generally combined with some preparation of opium; and if quinia was resorted to in cases that presented evidences of periodicity, it was usually fortified with opium.

This liberal use of the drug was not confined to cases of dysentery, but was extended to the other forms of flux.† When ordinary attacks of acute diarrhœa were treated at first with purgatives, these were generally followed with opiates either alone or combined with astringents. Indeed the practice of suppressing or attempting to suppress such attacks at the very beginning with diarrhœa mixtures, in which considerable quantities of opium were united with various astringents, aromatics and cretaceous preparations, was only too frequently resorted to in certain quarters. So, too, in the chronic fluxes undoubtedly the majority of medical officers united opium with almost every medicine employed to check the progress of the disease, and in spite of the sad experience of failure, which became more and more universal as the war progressed, continued to make use of it, though with ever-diminishing hopes of success, "as the drug which at least alleviated, if it did not cure."‡

* TRIPLER—p. 33, *op. cit.*, p. 691, *supra:* "Opiates and astringents, in the beginning of the treatment, are worse than useless. They cause the loss of valuable time, lull one into a false security, aggravate the congestion already existing, and frequently convert a perfectly manageable disturbance of the economy into a formidable and intractable disease." As to anodyne enemata, he remarks: "I cannot say that I have seen any decided benefit from them"—p. 34. He admits, indeed, the use of "a few grains of Dover's powder," after the use of his saline mixture, to procure sleep if the patient is restless; and when there is much symptomatic fever, with dry skin, he sometimes used small doses of Dover's powder to determine to the surface, but only after the preliminary evacuations. When after the subsidence of the fever the disorder assumed a chronic form, if the bloody mucous discharges continued, he was fond of Hope's camphor mixture, and sometimes added a few drops of laudanum, "half a drachm, or less," to the enemata employed; but he did not recommend the internal use of opiates in chronic dysentery.

† See, in illustration of the use of opiates in the various forms of flux during the war, the reports, in Section II, of STORROW—p. 43, *supra;* SCHÜSSLER—p. 44; PENROSE—p. 45; WOODWARD—p. 51; WRIGHT—p. 62; COUES—p. 64; HOLSTON—p. 66; BELLOWS, SCHELL and WHITTINGHAM—p. 70; LEE—p. 71; HOUGH—p. 75; BLAKESLEE—p. 76; WHITE and MCDONALD—p. 77; WAINWRIGHT—p. 78; JEWETT—p. 79; BRETZ, HOYT and SCHEETZ—p. 80; BROWN—p. 81; MUSSEY, HARRISON and FORBES—p. 82; POTTER and BIGELOW—p. 83; STRONG—p. 84; REYNOLDS—pp. 84-85; JONES, WHITE and MCCLURE—p. 85; GRIMES—p. 86; TAYLOR—p. 87; WALTON—p. 88; BEACH—p. 89; FOOTE, TOMPKINS, MCMILLEN and TUTTLE—p. 90; PYLE and BLADES—p. 91; MORSE and MCELROY—p. 92; COOPER, WALTON, COOK and GAGE—p. 93; WHITMIRE and HUNT—p. 94; FARQUHARSON—p. 95; WELCH—p. 96; and BRADT—p. 100. See also many of the reports of those cases in Section III in which a record of the treatment has been preserved. There were, however, always from the very first a certain number of medical officers who held for both acute and chronic fluxes the view expressed for the latter by DEBRULER—p. 42, *supra*—that "mercurials, opiates, and the ordinary astringents have been worse than useless, except so far as the opiates served to relieve pain or temporarily to check the bowels."

‡ SANFORD B. HUNT—*Camp diarrhœa and dysentery*, in Contributions relating to the causation and prevention of disease, and to Camp diseases, &c., published for the U. S. Sanitary Commission, New York, 1867, p. 395—uses the expression cited, after presenting his own testimony as to the futility of the means of treatment generally employed. He relates correctly that "it came to be a fixed doctrine at southern and southwestern stations, that confirmed cases had no security for cure except by removal to the north;" and adds, "among patients not thus removed, but treated in southern hospitals, much vacillation and irresolution were exhibited in the prescriptions of surgeons; as happens in all diseases the treatment of which by drugs is usually unsuccessful. To trace the history of an individual case, was to find that the prescriber had run the rounds of all remedies, from opium to astringents, from astringents to quinine, from quinine to bismuth, and from bismuth to nux vomica, from nux vomica to mercurials; returning almost always to opium as the drug which at least alleviated, if it did not cure." The same author gives his testimony—p. 304—that cathartics, especially Epsom salt and castor oil, were largely used during the war in the treatment of the early stages of the acute forms of diarrhœa and dysentery; and adds, "constipation preceded

For myself, I freely confess that I went into the field at the beginning of the war with predilections in favor of the use of opium in all the alvine fluxes, which experience very speedily modified. When I published my Outlines of the Chief Camp Diseases, in the latter part of 1863, I still favored its employment in a more liberal manner than I can now approve; but already at that time I insisted that opiates should not be "regarded as specific or curative agents" either in acute dysentery or the chronic fluxes, and that their use should be restricted to the fulfilment of two indications, namely, to relieve pain and to procure sleep.* Subsequent experience and study have inclined me more and more to the belief that even for these purposes it should not be indiscriminately resorted to in the fluxes, but should be reserved for those cases in which the urgency of the symptoms and failure to obtain relief in other ways make its use really indispensable.

A few physicians have maintained the hypothesis that opium is capable of exercising a directly curative influence upon the intestinal inflammation; but that it can actually do so, or that, indeed, it can ever cure any inflammatory process, has long been controverted by almost all those who have studied its actions most closely.† An examination of its

---

most of the cases, but, whether it had or not, it was found that a thorough purgation of the bowels from all irritants was the best and most speedy method of securing rest and opening the way for the successful administration of opiates." See, also, the testimony of Surgeon CHARLES H. RAWSON—*Health of the Army of the Mississippi*, Amer. Med. Times, Vol. IV, 1862, p. 312—who says, speaking of the diarrhœa of that army when in the vicinity of Corinth: "I have had occasion to use nearly all the remedies recommended, and of these I find opium stands at the head, and then one can combine it with bismuth, acetas plumbi, and tannin." Although, on account of the liberal use of opiates in other diseases and with the wounded, the figures give no notion of their use in the fluxes, the reader will be interested to learn that, according to the statement of Surgeon SPENCER, cited p. 768, the following quantities were purchased by the Purveying Department during the war: Opii pulvis, 552,196 oz.; opii tinctura, 828,258 oz.; opii tinct. camphorata, 993,311 oz.; pilulæ opii, (U. S. P.,) 813,156 dozen; pulv. ipecac. et opii, 447,151 oz. These quantities represent 43,404 pounds of opium, or rather more than twenty-one and a half tons, (of 2,000 lbs.,) besides which 27,200 ounces of sulphate of morphia were purchased, so that it must certainly be admitted that the pain-lulling drug was lavishly supplied for the relief of our suffering soldiers.

* WOODWARD—p. 229, *op. cit.*, p. 606, *supra*. With regard to acute dysentery, I wrote: "The use of opium in this complaint is to be regarded as limited chiefly to two simple indications. It is to be employed to relieve pain and to procure sleep. For the first purpose it is to be given in small and repeated doses, combined with whatever other medicament may be deemed advisable; for the second it is to be administered in full dose at bedtime. Opiates are not to be regarded as specific or curative agents. It is true, they control the frequency of the stools, but they may do so to a marked extent without exerting any favorable effect upon the progress of the disease." With regard to the chronic fluxes, I wrote—pp. 259 and 260: "The question of the use of opiates has excited considerable difference of opinion among military surgeons during the present war. While some administer them invariably, and with a freedom which borders on recklessness, others go so far as to exclude them altogether from their plan of treatment. The truth probably lies as ever between the two extremes. In cases in which the discharges are accompanied by griping or abdominal pain, opiates in moderate quantities are almost always admissible for the purpose of giving relief from this symptom. In this class of cases, they should be administered, combined with the other remedies employed, in moderate doses, frequently repeated, the quantity given being regulated by the violence of the symptoms and by the susceptibility of the patient. So also in cases attended by restlessness and sleeplessness at night, opiates may be administered in full doses at bedtime for the purpose of procuring sleep. Except under the above circumstances, however, they should be avoided as a general rule, as exercising little or no curative influence over the disease, and as liable, by interfering with the already impaired digestion, to do positive harm."

† Thus, for example, VOGLER—Kap. VII, S. 170, *op. cit.*, p. 738, *supra*—assumed a direct antiphlogistic power for opium. He writes: "Er wiedersteht offenbar Fieber und innerlichen Entzündungen. Ich habe in unzähligen Fällen Gelegenheit gehabt, die auffallend antiseptischen und entzündungswidrigen Würkungen desselben in dieser Krankheit zu bewundern." J. ARMSTRONG—*Some obs. on the utility of opium in certain inflammatory disorders*, Trans. of the Associated Apothecaries and Surgeon-Apothecaries of England and Wales, Vol. I, 1823, p. 309 *et seq.*—"prescribed large doses of opium, conjointly with bloodletting" in "acute and sub-acute abdominal inflammation," and declared that in efficacy this treatment "considerably exceeded that of any other remedy tried under similar circumstances"—p. 310; and CHRISTISON—*On the employment of opium for arresting internal inflammations*, London and Edinburgh Monthly Jour. of Med. Sci., Vol. I, 1841, p. 91—held that "opium may be employed for arresting acute internal inflammations in several ways. It may be given either alone, or along with ipecacuan, or in aid of general blood-letting." These opinions merely represent a modern heresy; they find no support among the ancient physicians, and among the moderns are advocated by comparatively few. Indeed, a diametrically opposite opinion has been accepted in many quarters. Thus GEORGE YOUNG—Sect. 34, p. 140, *op. cit.*, p. 739, *supra*—declared that "it is certainly a good general rule, that opium does harm in all internal inflammations, such as the phrenitis, pleuritis, angina, peripneumonia vera and notha, hepatitis, inflammation of the stomach, intestines, or any other internal part;" and elsewhere remarked—Sect. 39, p. 169: "I had established it as a general rule, that opium was improper in all those diseases in which bleeding was necessary." CULLEN—Vol. II, p. 238, *op. cit.*, p. 740, *supra*—was "persuaded of the propriety of Dr. Young's general rule;" and our own CHAPMAN—*Elements of Therapeutics and Materia Medica*, 4th Ed., Philadelphia, 1825, Vol. II, p. 169—though he made "many exceptions," as indeed both YOUNG and CULLEN did also, admitted that "as a general rule this is undoubtedly correct." (I note, by the way, that CHAPMAN appears to have confounded GEORGE YOUNG with THOMAS YOUNG, the originator of the undulatory theory of light, for he speaks of him as "a late writer of some distinction,"—*loc. cit.*—which would apply to the latter, but hardly to the former author when CHAPMAN wrote.) The necessary space cannot be taken in this place, nor indeed is it at all desirable here, to discuss in detail the literature of the use of opium in inflammation. I suppose no one at the present time seriously holds to the antagonism suggested by YOUNG, or would hesitate to give opium to a patient, if there was any reason for doing so, merely because he had an inflammation. On the other hand, belief in any direct antiphlogistic action of opium is at the present day pretty generally abandoned. We may readily agree with STILLÉ—Vol. I, p. 855, *op. cit.*, p. 711, *supra*—that the "local inflammatory symptoms are frequently aggravated and perpetuated by concomitant states of the general system," which may be benefited by opium, and that in such cases it may be regarded as "indirectly tending to cure the inflammation;" but it is equally true that there are concomitant morbid states of the general system, as well as concomitant local troubles, that are aggravated by the use of opium, and under such circumstances its use is "indirectly" injurious to the inflammatory process. G. B. WOOD—*A Treatise on Therapeutics*, &c., 2d Ed., Philadelphia, 1869, Vol. I, p. 743—regarded opium as an indirect arterial sedative, because a diminution in the frequency of the pulse follows in a short time the excitement produced by a full dose. "A diminution in its force, also, comes on after a time; and a positive depression of the circulation is thus effected." For these reasons he looked upon opium as useful in inflammation; nevertheless he recognized that "its first stimulant action, however, is in the way," and admitted that it should not be employed till the

effects upon similar inflammations within the reach of the observer's eye, for example, catarrhal and diphtheritic inflammations of the throat, will serve to indicate the futility of such hopes; and all who have witnessed numerous autopsies during epidemics of dysentery, must have repeatedly observed the most deplorable evidences of destructive inflammation in the intestines of subjects treated with opium in unstinted doses, for days or even weeks before death, with the effect indeed of blunting their sensibility to pain, but without exercising any apparent influence upon the progress of the disease.

Not only is it vain to hope for any direct benefit to the local inflammatory process from the use of opium, but the physician should distinctly recognize that there are several ways in which this drug is liable to prove injurious in dysentery. Chief among these, it is to be observed that, whenever in this disease the power possessed by opium of diminishing the peristaltic action of the intestines is carried to the extent of temporarily checking the stools, the fermenting or putrefying matters composing them are retained in contact with the inflamed mucous membrane of the lower bowel, where they must tend to intensify the inflammatory condition, and even to transform simple catarrhal processes into diphtheritic dysentery. Moreover, the use of opium is prone to aggravate the digestive disturbances that already exist; the belief expressed by some that it diminishes the hepatic secretion, which would constitute a serious objection to its use, does not appear to rest upon a very

force of the circulation has been subdued by treatment, or has subsided in the course of the disease. But the more we learn by exact observation of the action of opium upon the circulation, the more improbable it becomes that this action can of itself be beneficial in inflammation. A. BORDIER—*Des nerfs vaso-moteurs ganglionnaires*, Paris Thesis, No. 72, 1868, p. 72 *et seq.*—has studied with the sphygmograph the effects of moderate doses of opium (5–20 centigrammes daily) upon the human circulation. His observations show that the full, apparently strong, slow pulse, that so generally follows in a short time the use of opium, owes these qualities in fact to a considerable diminution in the arterial tension. In the most marked cases the lever of the sphygmograph rose almost vertically two or three times as high as in the normal condition, and in its oblique descent the increased dicrotism characteristic of feeble tension was distinctly seen. In one of his cases, either because the dose was larger or the examination made later, the pulse was more frequent instead of slower; but the sphygmograph gave the same evidence of diminished arterial tension. I refer the reader to the work cited for the reasoning by which BORDIER endeavors to show that these results depend upon vaso-motor paralysis, and that the effects of opium are comparable to those produced by the section of the great sympathetic nerve. The accuracy of his conclusions in this direction does not concern us here; but if it be true that the effect of opium is to diminish the arterial tension, we know that this phenomenon is accompanied by an increased velocity of the circulation (see E. J. MAREY—*Phys. Méd. de la Circulation du Sang*, Paris, 1863, p. 157) which can hardly be imagined to be otherwise than injurious to the inflamed part. In a recent lecture Professor G. SÉE—La Tribune Médicale, année X. 1877, p. 76—has criticised the observations of BORDIER, declaring that in the first stage of the action of opium the pulse is excited and the arterial tension increased; in the second stage the pulse retarded and irregular, but the tension still the same. I know not on what experimental evidence, if any, this statement is based. On the other hand, H. SCHÜLE—*Sectionsergebnisse bei Geisteskranken*, &c., Leipsic, 1874, S. 50—from sphygmographic traces taken after the administration of hypodermic injections of morphia to insane patients, has also come to the conclusion that indications of a diminished arterial pressure (die Momente einer geschwächten Arterien-Innervation) result, although I note that his curves—Taf. IV, Figs. 12–19—seem to show precisely the reverse of BORDIER'S. The diminished pressure inferred by these experimenters has been actually measured on animals by the manometer. R. GSCHEIDLEN—*Ueber die physiologischen Wirkungen des essigsauren Morphiums*, Unters. aus dem physiologischen Laboratorium in Würzburg, Theil II, 1869, S. 33—using a mercurial manometer directly applied to the arteries of dogs and rabbits, found that the injection of acetate of morphia subcutaneously, or into a vein, was usually followed by a diminished blood pressure. This was occasionally preceded by a considerable increase of the pressure, but generally any such temporary increase was inconsiderable and speedily followed by a fall. GSCHEIDLEN emphasizes the circumstance that in his observations the increased blood pressure, when it occurred, was not always accompanied by corresponding changes in the frequency of the pulse, and hence infers that it is not through the blood pressure, but, as he concludes from subsequent experiments, by a central influence exerted through the vagus that the changes in pulse frequency following the action of the drug are determined. In his still more recent experiments, WITKOWSKI—*Ueber die Morphiumwirkung*, Archiv für Exp. Path. u. Pharm., Bd. VII, Heft 3, 1877, S. 253—arrived at the conclusion that every hypodermic injection of morphia is followed by more or less (sometimes quite slight) diminution of the arterial pressure; he measured it with the kymographion of Ludwig, on dogs, cats and rabbits, curarized and artificial respiration kept up, and regards it as probably the result of a dilatation of the peripheral bloodvessels determined by central influences. Lastly, I may refer to the essay of P. PICARD—*Sur l'action de la morphine chez les chiens*, Comptes Rendus, T. LXXXVI, 1878, p. 1144—who affirms that relaxation of the small peripheral arterioles, after the administration of morphia, is readily measured in frogs by means of a micrometer; that in vigorous dogs this dilatation, and the consequent diminution of the normal resistance to the blood stream, is so great as to permit the cardiac pulse to be recognized in the jugular veins; and that the use of the manometer confirms this view. He concludes: "Tous ces faits ont évidemment la même signification: ils expriment la dilatation des vaisseaux et la diminution des résistances au cours du sang qui en est la conséquence." PICARD emphasizes the important fact that the considerable diminution in the mean pressure of the arterial blood (l'abaissement considérable de la pression moyenne) in dogs under the influence of morphia coincides, after the action is fully established, with considerable diminution in the frequency of the heart beats; and he reports that both phenomena continue to be observed after the pneumogastric nerves are cut. From these facts, and from experiments relating to the action on the pupil, he concludes: "Il faut donc admettre que la morphine a paralysé partiellement le système nerveux d'excitation du cœur en même temps qu'elle mettait dans un état identique le sympathique des vaisseaux et celui qui commande la dilatation de la pupille." Now, although I will readily concede that these interesting observations are insufficient to establish positively that opium is *per se* injurious to the inflammatory process, it may safely be affirmed that they demolish completely any speculations which endeavor to support the notion that opium acts as an antiphlogistic by appealing to its effects upon the circulation. My esteemed friend H. C. WOOD—p. 213, *op. cit.*, p. 675, *supra*—presents the question of the effect of opium upon the inflammatory process from a more reasonable point of view when he writes: "By allaying irritation and pain, opium affords relief in most cases of inflammation," though I should like to qualify the statement by saying many cases, instead of most, for there are probably many cases also in which its other operations do more harm than the good produced by its anodyne virtues; but when he adds that in certain varieties of inflammation "it seems to do much more than this, exerting, in some way at present difficult to explain, a life-saving influence," I must confess that I know of no evidence that supports such a belief.

sure foundation;* but it is a fact, which every physician of experience in this disease must have frequently noticed, that it often renders the anorexia more extreme and increases the tendency to nausea and vomiting. These are objections to its use even for a short time in dysentery; but when the disease is prolonged for several weeks, as is so often the case, the daily use of opium is furthermore prone to produce a condition of system, the result of chronic opium intoxication, which is certainly unfavorable to recovery. At the same time it should be recollected that, as was well known by the older physicians,† the griping pains and distressing tenesmus of dysentery can very generally be relieved by prompt resort to the use of evacuants and other suitable measures,‡ so that whenever this is possible it is clearly unnecessary to incur the dangers just indicated.

But it will sometimes happen that, in spite of the most judicious use of other measures, the sufferings of the patient continue to be so great that it becomes imperative to resort to some anodyne for their relief; and although opium is by no means the only drug that answers this indication, it is undoubtedly the most uniformly successful, and will very often afford a respite from present distress when all other means fail. Under such circumstances the judicious practitioner will not hesitate to employ this powerful drug to give

* J. PEREIRA—*Elements of Mat. Med. and Ther.*, 3d Amer. Ed., Vol. II, Philadelphia, 1854, p. 1041—attributed the constipation produced by opium in part to the diminished secretion of bile he supposed it to determine. In support of this view he says: "Sprœgel found the choledic ducts of animals, to which opium had been given, filled with bile; yet it had not passed into the intestines, for the fœces were scarcely tinged by it, but had the appearance which we observe them to have in jaundiced patients." STILLÉ, also—Vol. I, p. 830, *op. cit.*, p. 711, *supra*—says of opium constipation: "It is probable, also, that, as observed by Sprœgel, the diminished secretion of bile may contribute to this effect," &c. In a foot note to this passage he adds: "Quoted by PEREIRA, *op. cit.*, art. Opium." But PEREIRA had never read SPROEGEL, for he himself adds to the passage cited above: "Quoted by Christen, *Opium hist.*, etc., p. 66, 1820." I have not been able to see the work of C. A. CHRISTEN—*Opium historice, chemice atque pharmacologice investigatum*, Vienna, 1820—but have no doubt that PEREIRA cites it correctly, for in a review of it by ANTHONY TODD THOMSON—The Edinb. Jour. of Med. Sci., Vol. III, 1827, p. 376—I read: "Dr. Christen, however, points out some facts, which are exceptions to the general rule, that 'opium suppresses all the secretions.' Thus, as Linnæus (*Amœn. Acad.*, viii. 298) asserted, the flow of milk is not impeded but augmented by opium; the secretion of the bile is also increased, although the excretion is diminished, (*Jahn*, ii. 207);" and "Sprœgel remarked, that in animals feeding upon opium, the ductus choledochus was turgid with bile, whilst the alvine evacuations, like those of individuals labouring under jaundice, were scarcely coloured." Nevertheless, in the work referred to—J. A. T. SPROEGEL—*Experimenta circa varia venena in vivis animalibus instituta*, (1753;) I cite from the reprint of HALLER—*Disp. ad Morb. Hist. et Cur.*, T. VI, Lausanne, 1758, p. 557 *et seq.*—I not only am unable to verify the statement of CHRISTEN, but find directly the opposite asserted. SPROEGEL, indeed, reports that he found on dissection in several instances the gall-bladder full of bile, but he also reports generally the presence of a notable quantity of bile in the intestine, and even in the stomach, and was so struck by this circumstance that he declares it to be characteristic of opium poisoning: see Exp. 24, p. 563, in which, describing the dissection, he writes: "Ventriculus aqua flava, subnigra repletus erat, non vero inflammatus, intestina bile plena, uti semper in animalibus opio interemtis, nullum vero in his visceribus inflammationis signum adparuit." As against these misconceptions I may cite P. A. CHARVET—*De l'Action comparée de l'Opium*, &c., Paris, 1826, p. 217—who made great numbers of experiments on animals, and who, after pointing out that the use of opium is followed by neither yellowness of the conjunctiva or skin nor by clay-colored stools, and that nothing has been observed that indicates a diminution of the biliary secretion, adds: "J'ai ouvert un grand nombre d'animaux de différentes classes, empoisonnés par l'opium, et je n'ai jamais vu, chez ceux qui ont une vésicule biliaire, qu'elle fût moins pleine qu'à l'ordinaire. D'ailleurs, je répète que la coloration, brune ou jaune, des matières excrémentitielles, semble mettre hors de doute la non-suppression de cette sécrétion." So likewise H. NOTHNAGEL—*Handbuch der Arzneimittellehre*, Berlin, 1870, S. 6—testifies: "Ueber das Verhalten der Abscheidung des Darmsaftes und der Galle ist beim Menschen nichts Sicheres festgestellt. Die Farbe des Stuhls ist in der Regel unverändert." And R. BUCHHEIM—*Lehrbuch der Arzneimittellehre*, 3te Aufl., Leipsic, 1878, S. 465—expresses the opinion that it is still questionable whether the use of opium diminishes the intestinal secretion; that the constipation it produces in healthy persons is due merely to retardation of the peristaltic motion of the bowels, and that there is no evidence that it affects the liver: "Auch die Leber wird, so viel wir bis jetzt wissen, durch die Opiumbestandtheile nicht verändert." I will not attempt to give here a complete list of the works treating of the physiological effects of opium whether on man or animals, but merely subjoin the titles of those I have found of interest while preparing these pages. The learned work of TRALLES—Sect. I, Cap. 2, p. 49 *et seq.*, *op. cit.*, p. 737, *supra*—contains a chapter entitled, *Phænomenorum omnium succincta recensio, quæ opium assumtum in corpore humano insequuntur*, which is rich in references to the earlier observations and opinions. For the progress of subsequent inquiry I have consulted, in addition to the works already cited in this and the previous note, CULLEN—Art. *Opium*, Vol. II, p. 224 *et seq.*, *op. cit.*, p. 740, *supra;* JOHN LEIGH—*An experimental inquiry into the properties of opium*, &c., Edinburgh, 1786. (This essay, which gained the Harveian prize for 1785, and is dedicated to "George Washington, Esq.," is of special interest to the American reader, because its author was a countryman of ours;) SAMUEL CRUMPE—*An Inquiry into the Nature and Properties of Opium*, London, 1793; J. B. G. BARBIER—*Traité Elémentaire de Mat. Méd.*, 4me Éd., T. III, Paris, 1837, p. 1 *et seq.;* TROUSSEAU et PIDOUX—T. II, p. 11 *et seq.*, *op. cit.*, p. 716, *supra;* A. KÖLLIKER—*Phys. Unters. ueber die Wirkung einiger Gifte*, Virchow's Archiv, Bd. X, 1856, S. 244 *et seq.;* J. F. H. ALBERS—*Das Opium u. Affium*, &c., same Jour., Bd. XXVI, 1863, S. 225 *et seq.;* W. BAXT—*Die physiologische Wirkung einiger Opium-Alkaloide*, &c., Archiv für Anat., Phys. u. wiss. Med. Jahrg. 1869, S. 112 *et seq.;* J. HARLEY—*The Old Vegetable Neurotics*, London, 1869, Chap. 4, p. 99 *et seq.;* S. WEIR MITCHELL—*On the effect of opium and its derivative alkaloids*, The Amer. Jour. of the Med. Sci., Vol. LIX, 1870, p. 17; and CLAUDE BERNARD—*Leçons sur les Anesthésiques et sur l'Asphyxie*, Paris, 1875, p. 163 *et seq.* References to a number of other papers are appended to the essay of WITKOWSKI, cited last page.

† Note, for example, with what care HILDANUS—Cap. 9, p. 684 *et seq.*, *op. cit.*, p. 644, *supra*—insists that an effort should be made, 1, to remove the cause of the pain, and, 2, to mollify the acrid and malignant humors which produce it, before resorting, 3, to drugs which stupefy the sensibility of the part. Under 1, he counsels emetics, purgatives, diuretics and sudorifics, besides venesection, the application of cups, &c. Under 2, emollient drinks, such as milk, emulsion of sweet almonds and whatnot, as well as enemata of the same character. Only if these measures fail (si dolor his medicamentis non sedatur) does he commend such anodynes as syrup of poppies, Philonium, theriaca and the like. With this chapter, which well represents the views of the best instructed physicians of the seventeenth century, compare the declaration of CULLEN—cited p. 740, *supra*—that it is only the neglect of purging that renders opiates very necessary, and the recent report of MÉRY—*op. cit.*, p. 708, *supra*—with regard to the great relief of the tormina, tenesmus and other painful symptoms of dysentery afforded by the use of sulphate of soda.

‡ Such as enemata, concerning which vide *infra*, warm fomentations, rubefacients, &c.

relief, but he will always remember the dangers to which its operation exposes his patient, and will endeavor to avert them by proper precautions.* The injurious effects of locking up ammoniacal or other products of decomposition in the alimentary canal may be reduced to a minimum by the simultaneous or alternate employment of adequate doses of suitable purgatives; and chronic opium intoxication may be avoided by suspending the administration of the drug as soon as possible, or by alternating it with other anodynes.

It may sometimes also be necessary to resort to opium in dysentery for the purpose of procuring sleep, but it should not lightly be employed with this object. Sleeplessness, like pain, will very often yield to the judicious use of evacuants, and in other instances can frequently be controlled by bromide of potassium. But there are cases in which these measures fail to give relief, and in which the sleeplessness and restlessness of the patient become a source of danger. In such cases opium often proves to be the best hypnotic at our disposal, and may be resorted to without hesitation, in conjunction, however, always with the precautionary measures just referred to. Whether it may not, besides, be advisable sometimes to resort to opium for the purpose of moderating, without actually suspending, the intense activity of the peristaltic action which is not unfrequently observed, is a more doubtful question; but, in a general way, when these movements are painful, they fall under the rules relating to pain; when not painful, it is probably better on the whole to resort to other modes of treatment.

The choice of the preparation to be employed, when the use of opium has been determined upon, is probably in the majority of cases a matter of little moment. The solid drug, its extract, tincture, or the salts of morphia, can generally be employed indifferently,† and only in a few patients will experience show that some one preparation is better borne or produces more agreeable effects than another. Where such idiosyncrasies are known to exist they should be respected; and when in other cases the preparation selected appears to disagree, and the indications for the use of an opiate continue urgent, some one of the others may often be substituted with advantage, or other anodynes may be beneficially combined. With regard to the dose, a good deal must be left to the judgment of the practitioner. When the object is to allay pain, the dose should be given at such intervals as to keep the patient fairly under the influence of the drug, and a very moderate quantity at a time will usually be sufficient. When it is desired to procure sleep, a single adequate dose should be administered about half an hour before the usual bedtime.

In some cases, perhaps chiefly those in which the relief afforded by opium is most needed, the patient displays a marked insensibility to its influence. It is in this condition that heroic doses have so often been administered, and it is to be feared not always with the

---

* The dangers of the abuse of opium in unskilful hands were long ago insisted upon by WEDEL—Vol. II, p. 518, *op. cit.*, p. 737, *supra*—in striking language: "Sacra vitæ anchora est opium, bene et circumspecte agentibus: cymba autem Charontis in manu imperiti, et ceu gladius in manu furiosi;" and we may well use with regard to it the proverb which DEGNER—note, p. 230, *op. cit.*, p. 625, *supra*—applied to all potent medication in dysentery: "Clava Herculis non valet nisi in manu Herculis."

† That is of course on the supposition that moderate doses are given, for when it comes to the immense doses that some physicians have ventured upon, I suppose there can be little doubt that the morphia salts are safer than an equivalent quantity of opium. CLAUDE BERNARD—p. 172, *op. cit.*, p. 746, *supra*—indeed, goes so far as to assert that if the dose of opium that will produce a fatal result in any animal be ascertained, it will be found that an equal dose of morphia will be borne with impunity. I have not referred in the text to any of the other alkaloids of opium, because as yet none of them are entitled to our confidence for the treatment of the fluxes. If it were true, as claimed by CLAUDE BERNARD—p. 181 *et seq.*, and p. 511 *et seq.*—that by means of narcein, narcotic and anodyne effects, equal or superior to those produced by morphia, could be obtained with less headache and other disturbances, that alkaloid would be an important addition to our resources. But a number of excellent observers, such as BAXT and HARLEY—both cited in note *, p. 746, *supra*—in the old world, S. WEIR MITCHELL—p. 26, *op. cit.*, same note—and J. M. DA COSTA—*Obs. on the action of narcein*, Pennsylvania Hospital Reports, Vol. I, 1868, p. 177—in the new, have obtained different results; and it seems probable that under the name of narcein substances of diverse properties, and probably by no means of simple composition, have found their way into the market. This is true also as to codeia, the third of the narcotic principles contained in opium. For information as to the separate action of these and the other so-called principles of opium the reader may consult especially the last five papers enumerated in note *, p. 746, *supra*.

impunity that has been boasted. This condition results rather from the circumstance that the drug is not absorbed than because the nervous system is insensible to its influence, and a resort to *hypodermic injections of morphia* in such cases seems much more reasonable than the reckless introduction of large quantities of opiates into the stomach where their subsequent operation must be a matter of uncertainty. Such injections produce the anodyne or soporific effect desired, promptly, efficiently, with a minimum quantity of the medicine; and there is no difficulty, by repeating them at proper intervals, in keeping up for a long time any desired degree of anodyne effect. This mode of administering morphia has been employed by Hunter in enteritis, by Behier in the diarrhœa of phthisis.* Eulenburg has used with advantage hypodermic injections of tincture of opium, and Legagneur of muriate of morphia in catarrhal diarrhœa.† Rinteln, some of the Frankfort physicians as reported by Schmidt, Prince, Gallaher and Washington‡ have resorted to morphia injections in acute dysentery; indeed, the two physicians last named attribute to them the power of curing the disease without other medication.

This method seems well worthy of further trial as likely to prove in many cases more satisfactory than the administration of opium by the mouth or rectum, and certainly should supersede the clumsy plan of dusting morphia salts on a blistered surface. Pletzer, Bois, Lorent, Erlenmeyer and Eulenburg have lauded this mode of giving morphia in various forms of peritonitis,§ and it seems probable that it would prove equally advantageous in the intercurrent local or general peritonitis that so often accompanies dysentery. I do not doubt the accuracy of the observations of those who claim that dysentery may be cut short by these hypodermic injections, nor, indeed, of those who report prompt cures after the internal administration of large doses of morphia or other preparations of opium; but such observations must refer to mild catarrhal forms of the disease, which can almost always be promptly relieved by evacuants, without exposing the patients to the risks inseparable from the use of opiates for this purpose.

---

* C. HUNTER—*Letter* to The Med. Times and Gaz., 1865, Vol. I, p. 612. The observations of BEHIER have been reported by C. CODRESCU—*De l'emploi des injections sous-cutanées dans des cas de vomissements, de diarrhée et de névralgies intercostales chez les phthisiques*, Paris Thesis, No. 118, 1865, p. 24. He obtained excellent results when the disease was not too far advanced, but remarks that it is vain to hope a happy result in the colliquative diarrhœas of the last stages. EULENBURG—*Die Hypodermatische Injection der Arzneimittel*, Berlin, 1867, S. 165—reports a case of diarrhœa dependent on intestinal tuberculosis in which subcutaneous injections of tincture of opium were vainly tried; and LEGAGNEUR—p. 33, *op. cit., infra*—after trying hypodermic injections of morphia in similar cases, concludes: "Il ne paraît pas très-efficace dans le traitement de la diarrhée des phthisiques."

† EULENBURG—S. 164, *op. cit.* H. LEGAGNEUR—*Du traitement de la diarrhée par les injections hypodermiques de morphine*, Paris Thesis, No. 476, 1876. He used the muriate of morphia for this purpose, and thought—p. 33—that it was best to begin with 5 milligrammes morning and evening, although most patients will readily permit the dose to be increased to 4 centigrammes a day. He concludes from his observations that this is a good mode of treating diarrhœa, and sometimes succeeds where all other means have failed. This essay contains also some interesting evidence with regard to the fact that saline and other purgatives in adequate doses will operate while the patient is still under the influence of the morphia salt—p. 11 *et seq.* P. A. HARTSEN—*Zur Therapie des Durchfalls*, Virchow's Archiv, Bd. LXI, 1874, S. 287—has also recommended hypodermic injections of morphia in diarrhœa, but only in case the flux is so severe (heftig) that the opium taken by the mouth passes through the alimentary canal without being reabsorbed.

‡ RINTELN—*Eine Ruhr-Epidemie im Amte Hausberge, Kreis Minden, im Herbste* 1865, Berliner Klin. Wochenschrift, Jahrg. III, 1866, S. 461—reports having injected ½ to ¼ of a grain of acetate of morphia in the vicinity of the navel in a few cases of dysentery for the relief of tormina, and with instantaneous results, but he did not regard the effect as sufficiently durable to replace the internal use of opium. H. SCHMIDT—*Jahresbericht über die Thätigkeit des ärztlichen Vereins im Jahre* 1870, Jahresbericht, &c., der Stadt Frankfurt A. M., herausgegeben von dem aerztlichen Verein, Jahrg. XIV, 1870, S. 292—reports that morphia injections were very commonly used that year in dysentery by the members of the society, both to relieve the pain and to diminish the frequency of the stools. DAVID PRINCE—*The abortive treatment of dysentery by salts and chloral*, St. Louis Med. and Surg. Jour., Vol. XII, 1875, p. 475—only employed the morphia injections as a means of enabling the stomach when irritable to retain the hydrate of chloral, which he recommends in the average dose of 30 grains combined with an ounce or two of Epsom salts. T. J. GALLAHER—*On hypodermic injections*, The New York Med. Jour., Vol. XIII, 1871, p. 548 *et seq.*—has reported three cases of sporadic (probably catarrhal) dysentery treated with hypodermic injections (¼–⅓ of a grain) of morphia. He remarks: "These cases show that not only the pain and tenesmus of dysentery may be instantly relieved by the hypodermic injection of morphia, but the disease itself may be entirely cured without the employment of any other remedy. The cure, too, is much quicker than by the usual method, and the administration of frequent doses of nauseous drugs obviated. From one to two injections, mostly but one, daily, is all that is required. I have resorted to this method also in semi-chronic forms of dysentery and diarrhœa, with entire success." J. E. WASHINGTON—*Magic effects of hypodermic puncture of morphia in cases of dysentery*, Nashville Jour. of Med. and Surg., Vol. XXII, 1878, p. 48—has also reported several cases of sporadic dysentery cured by hypodermic injections of morphia.

§ H. PLETZER—*Die hypodermatischen Injectionen*, Zeitschr. für pract. Heilk., Bd. I, 1864. S. 238—in puerperal peritonitis; A. BOIS—*De la méthode des injections sous-cutanées*, Paris, 1864, p. 23—in subacute peritonitis: E. LORENT—*Die hypodermatischen Injectionen*, Leipsic, 1865, S. 13—in tubercular peritonitis, peritonitis following perforation of the intestine, perityphlitis, &c.; A. ERLENMEYER—*Die subcutanen Injectionen der Arzneimittel*, 3te Aufl., Neuwied, 1866, S. 43—in puerperal and tubercular peritonitis; and EULENBURG—S. 168, *op. cit.*, note *, *supra*—in puerperal peritonitis.

Most of the physicians who have employed opium in acute dysentery have also made use of it in the chronic forms of the disease. The complex formulæ containing opium preserved by Galen were lauded in the cœliac flux as well as in dysentery.* For centuries Theriaca, Philonium and the like were made use of in chronic dysentery,† and the various laudanums of Paracelsus and subsequent physicians were employed for the same purpose.‡ In modern times opium has been administered to these chronic cases chiefly in combination with astringents, and its power of diminishing the activity of the peristaltic movements has perhaps been valued quite as much as its anodyne or soporific properties. Even such physicians as Berndt, Canstatt and Savignac, who have been most careful with regard to the use of opium in acute dysentery, have recommended it without hesitation in chronic cases;§ and it is to be feared the unwillingness to employ opium under these circumstances, which Tripler manifested,‖ has been by no means generally felt.

Yet precisely in these chronic cases our modern knowledge of the disease and of the drug would appear to indicate the importance of caution. No fact is better established with regard to the chronic fluxes than the diminished activity of the digestive processes during the progress of the disease; and next to their narcotic action, no property of opium or of the morphia salts is better known than the interference with the digestive function which accompanies their operation.¶ Moreover, the probability that constipation, artificially produced by opium during the progress of a chronic flux, may serve to light up an intercurrent acute diphtheritic dysentery, as constipation occurring accidentally so often does, should not be overlooked; and the danger of producing chronic opium intoxication, with all its attendant evils, is even greater in the chronic than in the acute forms of dysentery. In these chronic cases, therefore, opium should be regarded rather as an anodyne and hypnotic, which may occasionally be resorted to in times of urgent need, than as a medicine to be steadily and constantly employed, either alone or in combination with other remedies, with the vain hope that it will aid in effecting a cure.

It is unnecessary here to enter into a detailed history of the use of opiates in the various forms of diarrhœa.** For the most part this application of the drug has shared the fortunes of its use in dysentery, and those who have employed it in the one affection have also resorted to it in the other. It is, indeed, quite proper that the rules applicable to catarrhal dysentery should govern our action in the case of diarrhœas resulting from catarrhal inflammation of the intestinal mucous membrane; and the considerations that indicate the importance of caution in the use of opiates in the former complaint are, to a great extent, applicable to the latter. In diarrhœas resulting from mere irritation of the intestinal mucous membrane not amounting to inflammation, opiates can no doubt be given with greater impunity; but in this case they are still less necessary.

---

* See note §, p. 735, *supra.* † For Theriaca, see note ‖, p. 729, *supra;* for Philonium, see note §, p. 735, *supra.*

‡ For information with regard to some of these laudanums, see note ‡, p. 736, *supra.*

§ BERNDT—Hefte 3 u. 4, S. 231, *op. cit.*, p. 717, *supra:* "Das Opium ist aber ein wichtiges Heilmittel bei den Nachkrankheiten der Ruhr," especially when a chronic flux with ulcerated bowels ensues. "Hier gehört das Opium in Verbindung mit den Adstringentibus und der Milchdiät zu den hülfreichsten Mitteln." CANSTATT—Bd. I, S. 530-31, *op. cit.*, p. 717, *supra.* SAVIGNAC—pp. 376-77, *op. cit.*, p. 620, *supra*—not only declares that "l'adjonction de quelque préparation opiacée aux astringents, aux obturants, aux balsamiques que nous verrons indiqués dans la dysentérie chronique, rend leur action plus douce et plus assurée, et contribue avec eux à tarir les sécrétions intestinales;" but concludes his article on opium by lauding the employment of its extract in subacute and yet more in chronic cases, and mentions that he has witnessed its successful employment in doses as large as the patient can bear, continued for many days. I will not attempt to cite the numerous other authors who have commended the employment of opium in combination with the astringents in chronic dysentery; let it suffice here to refer to MARTIN—p. 714, *op. cit.*, p. 621, *supra;* MOREHEAD—p. 303, *op. cit.*, p. 657, *supra;* and BARRALLIER—p. 772, *op. cit.*, p. 603, *supra.*

‖ TRIPLER—*loc. cit.*, p. 743, *supra.*

¶ Note on this subject the striking experiments of CLAUDE BERNARD—p. 169 *et seq.*, *op. cit.*, p. 746, *supra.*

** For an introduction to the study of the early liferature of this subject I would refer the reader to the work of TRALLES—Sect. III, p. 211 *et seq.*—who has patiently discussed the use of opium in various forms of diarrhœa.

Nevertheless a very considerable number of modern practitioners make use of opium with a liberal hand in the treatment of diarrhœa. It is given alone, as well as in combination with divers astringents, aromatics and cretaceous preparations, forming the various diarrhœa mixtures which from time to time have enjoyed considerable popularity. Doubtless these remedies are often employed with impunity; indeed it may be conceded that in a vast number of cases they afford prompt, speedy and complete relief; but it may well be questioned whether they do not do positive injury in many others, and whether, in the class of cases that they appear to benefit most, equally speedy and complete relief could not be procured by other measures.* That they are often appealed to in vain is soon learned by the hospital physician, who will generally find that the majority of the cases of dysentery and severe diarrhœa that come under his observation were treated at the start in this way. It is well worthy of inquiry whether the proportion of these serious cases is not greater when opiates are freely resorted to at the commencement of what appear to be trivial diarrhœas than when other measures are relied on.

I confess, the more I learn of the behavior of such cases under treatment, the more I am inclined to advise that opiates should be as far as possible avoided. It may readily be admitted that there are cases in which they cannot be dispensed with; in which the griping pains continue, in spite of the administration of suitable evacuants, with such intensity as to justify a resort to this potent anodyne; but even in these cases it should be employed rather as a temporary means of allaying pain than with a view to any supposed curative effect, and should be accompanied or followed by suitable evacuants. Perhaps it is most frequently indicated in those cases of acute gastro-intestinal catarrh, which in this country are generally spoken of as cholera morbus. Here, the rapidity and severity of the vomiting and purging, as well as the intensity of the griping pains, seem to warrant the employment of an opiate; and yet the condition of the stomach renders its action exceedingly uncertain. Under such circumstances hypodermic injections of morphia have been lauded by Ashe and Von Græfe.† They have the advantage of promptness and of much greater certainty in their effect than can be hoped under these circumstances from the internal administration of the drug, and, moreover, they are less likely to impede the subsequent operation of evacuants or other measures that may be indicated.

Other anodynes and hypnotics.—Among the remedies of this class which have been made use of in the treatment of the fluxes, *hyoscyamus* was already employed by the Greek physicians. It figures, in connection with opium, in several of the formulæ commended by Galen as useful in dysentery and the cœliac flux, especially in the long-

* Here I may refer with approval to the testimony of Trousseau—Vol. III, p. 110 *et seq.*, *op. cit.*, p. 644, *supra*—as to the efficacy of the saline purgatives, especially sulphate of soda and Rochelle salt, in the treatment of catarrhal diarrhœa. I agree also with his commendation of the subnitrate of bismuth in the later stage of the disease. But I cannot accept his view that opium is desirable in what he calls "diarrhée nerveuse," which appears to me to be merely a variety of catarrhal diarrhœa, or in his "diarrhée par tonicité exagérée," as to the existence of which as an independent affection I may be permitted to express grave doubts; but I could well wish that those who think, with the great clinician, that opiates are desirable in such cases, would content themselves with his favorite dose, a single drop of the laudanum of Sydenham—p. 117.

† I. Ashe—*The subcutaneous injection of morphia in cholera*, Med. Times and Gaz., 1862, Vol. II, p. 644—reports two cases of cholera (he calls them Asiatic cholera, which is probably going too far) promptly relieved, the one by a single injection of 15 minims of liquor morphiæ acetatis, the other by two such injections. The cases occurred in the practice of Dr. Ricketts, of Birkenhead, who suggested the treatment. A. von Græfe—*Therapeutische Miscellen. IV. Ueber die hypodermatischen Einspritzungen als Heilmittel in der ophthalmologischen Praxis*, Archiv für Ophthalmologie, Jahrg. IX, 1863, Abth. 2, S. 63. In cholera morbus (Brechdurchfällen) he declares this remedy to possess a life-saving power: "Hier können die hypodermatischen Injectionen, wie ich mich thatsächlich überzeugt, eine lebensrettende Bedeutung erhalten." I note that W. Leube—*Krankheiten des Magens und Darms*, Ziemssen's Handbuch, Bd. VII, 2, S. 40—who boldly declares that not only in sporadic cholera but in acute, violent, gastric and intestinal catarrh no remedy is so effectual as opium given internally in the form of powder or tincture, does not even allude to the question of hypodermic medication in these conditions. Further on, in speaking of the treatment of ordinary intestinal catarrh, after advising the preliminary use of evacuants, he declares that the most important indication is to secure rest to the inflamed organ—S. 275; and adds that this result, as experience has shown in thousands of cases, can best be obtained by opium. It is a significant circumstance, that so many of those who share these views also agree with Leube in ignoring the most efficient mode of administering the drug in such cases.

celebrated Philonium.* To the same combination the virtues of the cynoglossus pills were due, a famous nostrum which Mesue lauded in catarrhal affections of the respiratory organs, and the physicians of the sixteenth and seventeenth centuries often employed in dysentery. This formula was still preserved in the French Codex of 1866, and Savignac acknowledged that he occasionally prescribed it in chronic dysentery.† For nearly two thousand years, therefore, combinations of opium and hyoscyamus have enjoyed the confidence of medical practitioners; and although during the present century they have been but rarely employed in the fluxes, it may perhaps be questioned whether some equivalent compound might not be brought into use with advantage.

More than twenty years ago I witnessed on several occasions, in the practice of the late Professor Joseph Carson, of Philadelphia, the excellent effects of a combination of extract of hyoscyamus with muriate of morphia given at bedtime to procure sleep in various painful affections;‡ and I have myself since that time repeatedly employed the same preparation with advantage in various complaints, among others in the acute intestinal catarrhs so common during our hot summers. The addition of the hyoscyamus always appeared to increase the hypnotic and anodyne effects of the morphia, to avert the tendency to constipation and to diminish the digestive disturbances that usually accompany the operation of that medicine. The chief objection to its use was the very variable strength of the extract of hyoscyamus, as found in the shops, which often rendered it necessary to increase the quantity added to a given quantity of morphia in order to produce the desired action.

---

* For these formulæ, see the passages cited in note §, p. 735, *supra;* for Philonium, see the same note. I may add that GALEN—*De simp. med. temp. ac fac.*, Lib. VIII, Cap. 20, [Ed. Kühn, XII, 147,]—described three varieties of hyoscyamus: one with black, a second with yellow and a third with white seeds. He commends the last only in medicine, declaring the two others to be poisonous. DIOSCORIDES—Lib. IV, Cap. 69, fol. 215, *op. cit.*, p. 623, *supra*—took the same view. According to him the seed, leaves and stems are all possessed of medicinal virtues, and he particularly lauded an extract prepared by drying in the sun the expressed juice of the whole plant. CELSUS used the leaves—Lib. VI, Cap. 6, Vol. II, p. 150, Ed. cited p. 656, *supra;* the seed—Lib. V, Cap. 25, same Vol., p. 49; the root—Lib. VI, Cap. 9, same Vol., p. 183; the juice—Lib. VI, Cap. 7, same Vol., p. 173; and a decoction—Lib. III, Cap. 18, Vol. I, p. 199.

† Cynoglossus pills are thus described by MESUE—*Grabadin*, Lib. I, Distinctio X, fol. 182, Opera, Venice, 1581: "Catapotia ad catarhum, coryzam, tussim, aliosque his succedentes affectus. Recipiunt myrrhæ, drach. vi. thuris drachm. v. opii, hyoscyami, ana drach. iiii. croci drach. i. et semissem, radicum linguæ canis, drach. iiii. et semiss. forma massam. Da a drach. semiss. ad drach. i." The commentator adds: "Has vocant aliqui alchaiber, alii de cynoglossa." It is not clear from this passage which variety of hyoscyamus or what preparation was used, but I suppose there can be little doubt that it was the seeds of the hyoscyamus albus, which were long used for this preparation. Indeed, as late as the beginning of the last century DALE—p. 181, *op. cit.*, p. 729, *supra*—writes of the hyoscyamus niger: "Internus ejus usus rarissimus est," and adds that the hyoscyamus albus is much milder and safer. According to QUINCY—p. 125, *op. cit.*, p. 730, *supra*—the composition of these pills was modified by FERNELIUS and RENODÆUS chiefly by the addition of castor and styrax, and it was from their writings that it was copied into the first dispensatory of the London College. He gives the formula as follows: "Take of the dried roots of hounds-tongue, [cynoglossus,] white henbane seeds and opium, each half an ounce; of mastich six drams; of olibanum five drams; of saffron, castor and styrax, each one dram and an half." I have said in the text that this formula is still preserved in the French Codex of 1866: see p. 554 of that work. I may add that it is marked with a star to indicate—see p. 29—that it is one of those articles that every drug store should keep on hand. It differs from the formula of QUINCY, chiefly, in containing myrrh, but no mastich or styrax, and in being made into a pill-mass with honey. Like the ancient preparation, it is made from the seeds of the hyoscyamus albus, for the formula reads "poudre de semences de jusquiame;" and elsewhere we learn—p. 62—"quant aux semences de Jusquiame, les seules que l'on trouve dans le commerce sont toujours blanches et appartiennent à la Jusquiame blanche." It would be idle to attempt to cite all the writers who have commended this preparation in dysentery: I will merely refer to NICOLAUS PISO—p. 277, *op. cit.*, p. 665, *supra*, and SENNERTUS—T. III, p. 175, *op. cit.*, p. 645, *supra*—as examples. The latter classes it with Philonium and the various laudanums. SAVIGNAC—p. 384, *op. cit.*, p. 620, *supra*—speaks of it as "les pilules de cynoglosse, vieux remède dont les propriétés calmantes peuvent encore être mises à profit, et que j'ai prescrit quelquefois dans le cours de la dysentérie chronique." He gravely adds that he believes the root of cynoglossus in this preparation serves rather to give a name to the formula than to increase its activity. At the present time the hyoscyamus niger is generally employed: for its commercial history see the *Pharmacographia*—p. 416, *op. cit.*, p. 703, *supra*. It may be remarked in addition that the extract of hyoscyamus has occasionally been prescribed in dysentery as a substitute for opium. Thus C. C. MATTHÄI—*Ueber die epidemische Ruhr*, Hannover, 1797, S. 165-66—states that he employed it even more frequently than opium; so far from constipating, it favored the action of the purgatives administered; but he admits that it was very variable in its action, and that especially the fresh extract was more active than after it had been kept some time.

‡ Professor CARSON used pills containing each ¼ of a grain of muriate of morphia and 2 grains of extract of hyoscyamus. One of the cases, in which I saw him employ them, made a deep impression upon my mind. It was an abscess in the abdominal walls over the region of the spleen, which I witnessed during the winter of 1858-59. The patient, a delicate young woman, happily delivered a few weeks before of her first infant, suffered excruciating pain, as I now suppose, from local peritonitis. The nature of the tumor, which speedily made its appearance, was not recognized for nearly three months, although several distinguished physicians and surgeons were called in consultation. At length fluctuation was recognized; the abscess was opened by Professor H. H. SMITH, and the patient made a speedy recovery. Professor CARSON attended this case with me, and, during three months of great suffering, kept the patient comfortable by the nightly administration at first of one, then of one and a half, and finally of two of the pills just described. Her bowels were seldom constipated, and then laxatives always acted readily. I note that T. H. TANNER—*The Practice of Medicine*, 5th American Ed., Philadelphia, 1870, p. 1104—commends a similar formula: "℞. Extracti opii gr. 1–4, vel morphiæ hydrochloratis, gr. ¼–1; extracti hyoscyami, gr. 5. Make into two pills, to be taken at bedtime. For the relief of severe pain, and to afford sleep in lingering diseases." A combination of acetate of morphia with extract of hyoscyamus was commended by the same author in his *Manual of the Practice of Medicine*, 1st American from the 3d London Ed., Philadelphia, 1858, p. 367.

The experiments of Harley* were quite in accord with this experience, and led him to the conclusion that opium prolongs and intensifies the effects of hyoscyamus, while hyoscyamus increases the hypnotic action of opium, and to a certain extent is able to avert the derangement of the vagus nerve, which is frequently the first effect of that drug. Recent physiological and chemical researches with regard to hyoscyamus, stramonium and belladonna seem, however, to render it more and more probable that the active principles of these drugs are after all identical;† and it will be shown further on that during the last ten years clinical experience with regard to the combined action of atropia and morphia seems to show that a mixture of these two alkaloids may be advantageously substituted for the more uncertain combination of morphia with extract of hyoscyamus.

Another drug of this class, occasionally used in the treatment of the fluxes, is *belladonna*. Conrad Gesner wrote from Zurich, in 1564, to his friend Achilles P. Gasser, that the inspissated juice of the fruit of this plant cures dysentery.‡ More than a century later J. L. Hannemann published in the German Ephemerides an account of the success of a certain Danish clergyman, who treated the cases of dysentery occurring in his parish with wine in which the same fruit had been infused.§ These observations were cited by Mangetus and Murray,‖ but do not appear to have attracted much attention until Bayle, in 1830, borrowed them from the work of Murray, and enumerated dysentery among the affections that belladonna cures.¶ Rognetta in 1838 repeated this statement on the authority of Bayle,** and in consequence of the publicity given to it by these two works a number

* Harley—p. 341 *et seq.*, *op. cit.*, p. 746, *supra*.

† On this subject see K. D. Schroff—*Ueber Hyoscyamin*, Wochenblatt der Zeitschr. der k. k. Gesellschaft der Aerzte zu Wien, Jahrg. II, 1856, S. 389 *et seq.*; G. Lemattre—*Recherches exp. et cliniques sur les alcaloides de la famille des solanées*, Arch. Gén. de Méd., T. VI, 1865, p. 39 *et seq.*; Harley—Chap. 8, p. 321 *et seq.*, *op. cit.*, p. 746, *supra*; Ch. Laurent—*De l'hyoscyamine et de la daturine*, Paris Thesis, No. 155, 1870; M. Hellmann—*Beiträge zur Kenntniss der phys. Wirkungen des Hyoscyamins und der Spaltungsproducte des Hyoscyamins und des Atropins*, Inaug. Diss. Jena, 1873. These observations show, to say the least, the great similarity of the effects upon the animal organism produced by hyoscyamia, daturia and atropia. Their effect upon the pupil, the respiration, the circulation, the motor nerves and reflex irritability appears to be the same. Some of the earlier of the authors cited, while admitting this similarity of their action, sought to demonstrate characteristic differences, for the most part, however, only quantitative; but their testimony in this direction is so contradictory as to make it probable the differences they observed were dependent merely on the relative purity of the samples used. Thus Schroff—S. 428, *op. cit.*—found hyoscyamin the most active of the series in its local effect upon the pupil, while Lemattre—p. 54, *op. cit.*—found atropia the most active of the three, and daturia next. More than all this, the experiments of Hellmann—*op. cit.*—seem to show that the similar chemical derivatives (Spaltungsproducte) of hyoscyamia and atropia are identical in their effects upon the organism. With regard to the chemistry of these alkaloids and their derivatives, see A. v. Planta—*Unters. über die Zusammensetzung einiger natürlichen organischen Salzbasen*, Annalen der Chemie u. Pharmacie, Bd. LXXIV, 1850, S. 245. Note particularly his analyses of daturin and atropin, from which he was led to identical formulæ for the two alkaloids. K. Kraut—*Ueber das Atropin*, same Jour., Bd. CXXVIII, 1863, S. 280, Bd. CXXXIII, 1865, S. 87, and Bd. CXLVIII, 1868, S. 236. W. Lossen—*Ueber das Atropin*, same Jour., Bd. CXXXI, 1864, S. 43, and Bd. CXXXVIII, 1866, S. 230. H. Hœhn u. E. Reichardt—*Ueber Gewinnung und Zusammensetzung des Hyoscyamins*, same Jour., Bd. CLVII, 1871, S. 28. These investigations show that hyoscyamia can be broken up by the action of various acids and bases, especially caustic baryta, into a base, hyoscin, and an acid, hycscin acid. In the same way atropia is broken up into tropin and tropic acid. The two acids appear to be identical in composition, while the two bases appear, like hyoscyamia and atropia, themselves to differ by the presence in the latter of two additional equivalents of carbon, a difference which perhaps may disappear on further investigation. On the basis of the chemical facts, so far as known, and of his own experiments on animals, R. Buchheim—*Ueber die pharmakologische Gruppe des Atropins*, Archiv für Exp. Path. u. Pharmakologie, Bd. V, 1876, S. 463 *et seq.*—has suggested that the drugs hyoscyamus, stramonium and belladonna, and their alkaloids may hereafter be classed together as *the atropia group:* see also, by the same author, *Lehrb. der Arzneimittellehre*, 3te Aufl., Leipsic, 1878, S. 478 *et seq.*

‡ Conrad Gesner—*Epist. Med.*, Zurich, 1577, Lib. I, fol. 34—called the plant Solanum Sylvaticum, and wrote: "Succum ex ejus fructibus (acinis, qui cerasa referunt) expressum et ad syrupi consistentiam cum pauco saccharo decoctum, ita efficacem esse, ut vel ligulæ, aut cochlearii parvi mensura somnum inferat, fluxiones sistat, dolores tollat, dysenteriam curet, gratus est plane, sed cavendum ne amplius detur, ego enim laude usus sum." This observation is cited among others by J. M. Faber—*Strychnomania*, Augsburg, 1677, pp. 23 and 48. According to the testimony of G. J. Welsch—*De vena medinensi*, Augsburg, 1674, Cap. 10, p. 270—Gasser prudently abstained from trying the new remedy.

§ J. L. Hannemann—*De dysenteriâ feliciter curata*, Ephem. Med.-Phys. German, Dec. II, an. III, 1684, Obs. 64, p. 154: "Hanc nostram Chersonesum Cymbricam plurimis in locis infestat dysenteria: adversus hunc morbum contumacissimum et contagiosissimum quidam Pastor in parochia sua decumbentibus summo cum fructu et successu propinavit vinum, cui infusæ sunt baccæ Solani, non solum enormem fluxum sistunt, dolorem demulcent, verum malignitatem in sudorem resolvunt." L. Schröck, in his scholium to this observation, declared that, notwithstanding the reluctance of Gasser, he himself should not hesitate to give this drug in suitable doses in the absence of other medicines. This observation and that of Gesner have generally been understood to refer to our atropia belladonna, which was formerly known as the solanum lethale: see Mangetus—T. II, p. 863, *op. cit.*, p. 736, *supra*, Art. "Solanum lethale dictum Bella Donna." The resemblance of its berries to cherries, mentioned by Gesner, is repeated by Stillé—Vol. I, p. 897, *op. cit.*, p. 711, *supra*.

‖ Mangetus—*loc. cit.*, last note. J. A. Murray—*Apparatus Medicaminum*, Vol. I, Gottingen, 1776, p. 432.

¶ A. L. J. Bayle—*Bibl. de Thérapeutique*, T. II, Paris, 1830, p. 380—professedly borrowed the article in which the observations of Gesner and Hannemann are cited from the work of Murray, whose Latin he evidently did not very well understand, for he makes the "pastor" of Hannemann "un berger danois," and on p. 514, attributes to Gesner the cure of "une dyssenterie intense."

** Rognetta—*Mém. sur les vertus thér. de la belladone*, Gaz. Méd. de Paris, T. VI, 1838, p. 584.

of physicians were induced to try the remedy. Fouquet found no benefit from its use.* Vogt thought small doses of the extract might sometimes be employed to relieve the tormina when it was desired to avoid the constipating effect of opium, and that in large doses it was preferable to opium for the relief of the vesical tenesmus.† Leclerc, during an epidemic of dysentery which prevailed in the garrison of Tours in 1856, applied large belladonna plasters to the abdomen with alleged advantage.‡ Savignac gave the extract internally with such excellent effect that he expresses wonder that it has not been more generally used. He particularly emphasized the circumstance that it did not tend to constipate the bowels, but on the contrary favored their action.§ A few years since Schwalbe employed sulphate of atropia internally for the relief of the tenesmus in the dysentery of Costa Rica, and with good results.‖

All these observations refer to the employment of belladonna or its alkaloid uncombined with other narcotics. But it is not in this way that the greatest advantage is probably to be expected from its use. Clinical experience as well as experiments on healthy human individuals indicate that, administered by itself, it is far inferior to opium in efficacy and certainty, whether as an anodyne or a hypnotic;¶ and for these purposes, therefore, it could not be judiciously substituted for opium or morphia in the treatment of the fluxes. But constantly accumulating evidence seems to indicate that a combination of the two drugs, and especially, in view of the uncertain strength of the extract of belladonna, a combination of the two alkaloids might often be employed with benefit in these diseases.

After the publication of the observations of Lipp and Anderson, a belief that these medicines were mutually antagonistic arose in many quarters, which undoubtedly retarded the recognition of the advantages of combining them. But numerous experimental researches

* A. FOUQUET—*De la Dysenterie*, Vannes, 1852, p. 152: "J'ai expérimenté a petites doses la belladonne dans la dysenterie; mais je n'en ai retiré aucun effet avantageux."

† VOGT—S. 187 u. 219, *op. cit.*, p. 645, *supra*.

‡ The experience of LECLERC has been reported by A. ANSALONI—*De la médication de la dysentérie aiguë épidémique, et d'un procédé thérapeutique pour arrêter le ténesme*, Paris Thesis, No. 39, 1859, p. 18 *et seq.* It was founded upon the belief that the tenesmus of dysentery is of a neuralgic nature, that it exercises a prejudicial influence upon the progress of the inflammation, and that the solanaceæ are excellent remedies in neuralgic affections. He applied to the abdomen a large plaster of the extract of belladonna, which he renewed every twenty-four hours. Sometimes he substituted for it the extract of stramonium. At the same time he administered calomel in broken doses internally, and in the more advanced stages of the disease nitrate of silver and opium. BARRALLIER—p. 773, *op. cit.*, p. 603, *supra*—reports that, imitating LECLERC, he habitually employed an ointment composed of extract of belladonna and lard for the relief of the tenesmus and abdominal pain of dysentery.

§ SAVIGNAC—p. 380, *op. cit.*, p. 620, *supra*—gave 10 to 20 centigrammes of the extract in the form of pills, and declared that it calmed the pains as well if not better than opium.

‖ C. SCHWALBE—*Klima und Krankheiten der Republik Costarica*, Deutsches Archiv für Klinische Med., Bd. XV, 1874-5, S. 171. He dissolved one centigramme of sulphate of atropia in 180 cubic centimetres of distilled water, and gave, when the tenesmus was severe, a teaspoonful every half-hour until dilatation of the pupil and dryness of the throat ensued. This method, he remarks, is far preferable to the application of a belladonna plaster to the abdomen for the same purpose.

¶ When belladonna or atropia, in full but not poisonous doses, is administered to a healthy person, it produces dilatation of the pupil, a sense of dryness in the mouth and throat and of burning in the skin; considerable debility, restlessness, headache and mental disturbance follow. Hallucinations are usual; often the patient is sleepless, or, if he sleeps, is disturbed with delirious dreams; sometimes, however, stupor is produced. See, for testimony with regard to these phenomena, C. D. SCHROFF—*Ueber Belladonna, Atropin und Daturin*, Zeitschr. der k. k. Gesellschaft der Aerzte zu Wien, Jahrg. VIII, 1852, Bd. I, S. 215 *et seq.*; HARLEY—Chap. 5, p. 238 *et seq.*, *op. cit.*, p. 746, *supra*; H. NOTHNAGEL—S. 57, *op. cit.*, p. 746, *supra*; STILLÉ—Vol. I, p. 900 *et seq.*, *op. cit.*, p. 711, *supra*; R. BUCHHEIM—*Lehrb. der Arzneimittellehre*, *loc. cit.*, p. 752, *supra*. FRONMÜLLER—*Weitere Unters. über die schlafmachende Kraft der Narcotica*, Deutsche Klinik, Bd. XVII, 1865, S. 381 u. 382—declared that atropia was unsuitable for use as a narcotic, and that he regarded its use for this purpose as dangerous; the same opinion is repeated in his later work, *Klinische Studien über die schlafmachende Wirkung der narkotischen Arzneimittel*, Erlangen, 1869, S. 88 u. 89. A. I. MEURIOT—*De la méthode physiologique en thérapeutique et de ses applications a l'étude de la belladonna*, (a work rich in the bibliography of the subject,) Paris Thesis, No. 68, 1868, p. 110—summed up the testimony accessible when he wrote in the following forcible words: "On a longtemps employé, en médicine, la belladonne comme narcotique, mais il est aujourd'hui reconnu que cette plante produit de la stupeur, du coma et non du sommeil." Subsequent experience has only served to confirm this opinion. As to its anodyne effects, the testimony is more contradictory. A vast number of observations might be collected to show its efficacy in the relief of neuralgia. HARLEY—Chap. VI, p. 268, *op. cit.*—indeed, goes so far as to declare, "In painful affections of the nerves, whether arising from functional disorder or inflammatory action, atropia used subcutaneously is the most valuable remedy that we possess. In my hands it has never failed to bring relief, and in all cases but one has finally removed the affection." On the other hand, S. WEIR MITCHELL, W. W. KEEN and G. R. MOREHOUSE—*On the antagonism of atropia and morphia*, &c., Amer. Jour. of the Med. Sci., Vol. L, 1865, p. 75—testify, on the basis of numerous hypodermic injections, that while morphia thus used is of the utmost value as an anodyne, "conia, atropia and daturia have no power to lessen pain." H. C. WOOD—p. 249, *op. cit.*, p. 675, *supra*—referring to the great clinical experience of MITCHELL, especially in nervous affections, writes: "Dr. Mitchell has had probably the best opportunities ever afforded for testing this, and he says decidedly that it [atropia] is of little use in severe suffering." WOOD adds that his own experience is to the same effect, and that although he admits it to be frequently useful in neuralgia, he believes that "belladonna is almost immeasurably below opium as an analgesic."

have established the fact that this antagonism is by no means such that the medicinal effects of the one are completely neutralized by those of the other;* on the contrary, it appears to be pretty well demonstrated that the addition of atropia renders it possible to use smaller doses of morphia, and obviates some of its objectionable tendencies. Brown-Séquard

* It would be out of place to attempt here a complete discussion of the question of the alleged antagonism between belladonna and opium, but a notice of the more important works on the subject and a few remarks seem called for. Attempts have been made to assign an antiquity to this notion which does not appear to be proven by the literature of the subject. G. GIACOMINI—*Trattato Filosofico-Sperimentale dei Soccorsi Terapeutici*, (1833-38;) I cite Opere, Vol. VII, Padua, 1854, p. 356—has stated that it was observed by PROSPER ALPINUS and DE LOBEL that, when united with opium, belladonna has a milder action: "Infatti erasi notato da Prospero Alpino e da Lobel, che unita all'oppio la belladonna ha azione più mite." The treatise of GIACOMINI was translated into French by MOJON and ROGNETTA, and from this source—translation cited Ed. of 1842, p. 537—the statement just mentioned has been copied by NORRIS, FERRAND, CAMUS, ERLENMEYER and some other writers—cited *infra*—without any question. I have taken some trouble to verify this statement, but without success. GIACOMINI cites PROSPER ALPINUS—*De Plantis Ægypti*, Cap. 42, p. 51—without mentioning the edition. Of this work I have carefully examined the Venice edition of 1592, and find on the folio cited the statement that the Egyptians use the solanum somniferum for procuring sleep, and in various diseases, but not the slightest reference to the effects of combining it with opium is to be found in any part of the chapter referred to. Moreover I have vainly searched the *Medicina Ægyptiorum*, Leyden Ed. of 1719, of PROSPER ALPINUS, especially Lib. IV, for the expression of any such opinion, and I suspect the learned Italian has in some way fallen into error. As to DE LOBEL, he does not give any reference, but I suppose him to refer to the joint work of this author and PENA—vide *infra*—which, however, merely mentions, among other alleged antidotes, the famous alexipharmic theriaca. WM. F. NORRIS—*Cases of opium poisoning treated by belladonna, with remarks*, The Amer. Jour. of the Med. Sci., Vol. XLIV. 1862, p. 395 *et seq.*—has brought forward observations from the works of PETRUS PENA et MATTHIAS DE LOBEL—*Stirpium Adversaria Nova*, London, 1570-71, p. 103; G. HORSTIUS—*Opera Med.*, Nuremberg, 1660, T. II, Lib. X, Obs. 4, p. 488; and J. M. FABER—*Strychnomania*, p. 18 *et seq.*, *op. cit.*, p. 752, *supra*—to prove that "a knowledge of the antagonistic powers of opium and belladonna seems also to be of early date." But these observations, which I have carefully examined in the editions just cited, do not fairly bear any such interpretation. They contain, it is true, accounts of a number of cases in which the poisonous effects of belladonna were combated among other remedies by theriaca; and I may add that GIACOMINI—*loc. cit.*—has correctly cited THEOPHILUS BONETUS—*Polyalthes*, Geneva, 1694, T. III, p. 575—as having in a more general way commended "alexipharmics" for the same purpose. For in truth in those days theriaca was regarded as an alexipharmic and antidote to the poisons generally, and it was not to the opium it contained, but to the whole mixture, vipers' flesh and all—see p. 730, *supra*—that its virtues were supposed to be due. NORRIS adds that FABER also cites a case from BROTBEQUIUS "of a similar kind, in which recovery took place after the exhibition of opium"—p. 400, *op. cit.* I have carefully examined this case in the work of FABER—Obs. XV, pp. 25-6, *op. cit.*—only to find that the preparations actually administered were compounded from theriaca and bezoar, "adhibitis theriacalibus et bezoardicis," so that the same criticism applies to this case as to the others. And this is also true of the next set of observations brought forward by NORRIS, viz., those of BOUCHER—*Sur cinq enfans empoisonnés par des fruits de bella-donna*, Jour. de Méd., Chir., Pharm., &c., T. XXIV, 1766, p. 310 *et seq.* The substance of this paper is correctly given by NORRIS, although he had not seen it, but borrows his statement from GIACOMINI. Emetics, purgatives, enemata, and above all vinegar, which he regarded as the true antidote, were the remedies used by BOUCHER: "Il paroît vérifié que les acides végétaux sont l'antidote du poison de la bella-donna et des plantes venéneuses de la même classe; et tout concourt à donner la préférence au vinaigre"—p. 328. NORRIS adds: "In two cases, however, one of which was in a state of coma, and the other delirious, preparations of opium were administered." This statement does not bear comparison with the original paper. The two patients referred to—"le petit Courat" and "la petite Margousin"—p. 316—received, it is true, after they had been sufficiently vomited and purged, a "mixture cordiale" composed of eau thériacale, the distilled water of linden flowers, &c. Now I need hardly remind the reader that eau thériacale, our old aqua theriacalis or treacle water—see p. 729, *supra*—was a distillate in which the opium was left behind in the still. The particular form of treacle water which BOUCHER used was probably that described in the 5th edition of LEMERY—*Pharmacopée Universelle*, Paris, 1761, p. 593—to which the reader is referred. I am therefore unable to acknowledge that the evidence brought forward shows the suggestion that opium may be used as an antidote in belladonna poisoning to be any older than the dissertation of J. LIPP, (J. H. F. AUTENRIETH, Præs.)—*De veneficio baccis belladonnæ producto atque opii in eo usu.* Tubingen, 1810—who, in the treatment of several cases of poisoning by belladonna berries, after first thoroughly evacuating the alimentary canal with emetics and purgatives, essayed the use of opium (in the form of Sydenham's laudanum) with apparent advantage—p. 4 *et seq.* Others were not slow in imitating this practice, for GIACOMINI in his article on opium—*op. cit.*, T. IV, Padua, 1853, p. 344—states that many Italian physicians had employed that drug in poisoning by belladonna, stramonium and hyoscyamus, and have seen the sopor dissipated, the delirium and convulsions calmed. The conception of a mutual antagonism between the two drugs appears to have originated in the suggestion of CORRIGAN, reported by GRAVES—*On the state of the pupil in typhus, and the use of belladonna in certain cases of fever*, The Dublin Jour. of Med. Sci., Vol. XIII, 1838, p. 351 *et seq.*—that narcotics which produce dilatation of the pupil (*e. g.*, belladonna) might prove advantageous in those cases of fever in which the pupil is contracted. GRAVES elaborated from this suggestion the doctrine that there are two kinds of cerebral excitation, very different in their nature, one attended with dilatation, the other with contraction of the pupil; opium may be advantageously used in the first, belladonna or stramonium in the second. It was this doctrine that suggested, as he himself tells us, to THOMAS ANDERSON—*On the influence of belladonna in counteracting the poisonous effects of opium*, The Monthly Jour. of Med. Sci., (Edinburgh,) Vol. XVIII, 1854, p. 377—the use of belladonna in opium poisoning, which he appears to have been the first to essay. After this date cases of opium poisoning treated by belladonna and of belladonna poisoning treated by opium multiplied in the journals. A number of them have been collected by NORRIS—*op. cit.*—who has also recorded two cases observed by himself, and concludes, "that in opium poisoning, belladonna in doses which in a state of health would certainly poison, may be administered with impunity and be followed by a rapid subsidence of the symptoms produced by the exhibition of the former drug, and *vice versa* that opium rapidly and safely counteracts the poisonous influence of belladonna." This paper of NORRIS and a previous one by C. C. LEE—*On the antagonistic effects of opium and the mydriatics*, The Amer. Jour. of the Med. Sci., Vol. XLIII, 1862, p. 54 *et seq.*—were made widely known in Europe through an abstract published in the Archives Gén. de Méd., T. III, 1864, p. 575, and gave rise to a good deal of discussion and experiment. The more important subsequent studies are those of E. CAMUS—*Étude sur l'antagonisme de l'opium et de la belladonne*, Paris Thesis, No. 124, 1865; MITCHELL, KEEN and MOREHOUSE—*op. cit.*, last note; FERRAND—*De l'antagonisme de l'opium et de la belladonne*, Bull. Gén. de Thér., T. LXX, 1866, p. 494 *et seq.*, (historical and critical;) ERLENMEYER—*Der Antagonismus zwischen Atropin und Morphium*, Berliner Klin. Wochenschrift, Jahrg. III, 1866, S. 13; HARLEY—Chap. VII, p. 269 *et seq.*, *op. cit*, p. 746, *supra*; H. C. WOOD—*Contribution to our knowledge of the phys. action of atropia*, The Amer. Jour. of the Med. Sci., Vol. LXV, 1873, p. 332; J. HUGHES BENNETT—*Report of the committee of the British Med. Ass. to investigate the antagonism of medicines*, British Med. Jour., 1874, Vol. II, p. 436 *et seq.*, reprinted as *Researches into the antagonism of medicines*, London, 1875; and H. HEUBACH—*Antagonismus zwischen Morphin und Atropin*, Archiv für Exp. Pathologie u. Pharm., Bd. VIII, 1877, S. 31. These investigations contradict each other as to many particulars in a manner that may seem to indicate the difficulty of the inquiry. It would carry me too far from my present purpose to enter into a discussion of details; let it suffice to express my admiration of the work of the Bennett committee, who conclude—p. 54, reprint cited *supra*—"that in dogs sulphate of atropia modifies the symptoms of poisoning by meconate of morphia, diminishes their intensity, and may even save life after a fatal dose of the latter. It is therefore decidedly antagonistic, but within a limited area." But I cannot agree with the subsequent remark that "in man, sulphate of atropia would be too dangerous and uncertain a remedy to depend on in cases of poisoning by opium or any of its salts, but where the heart's action is greatly diminished it is directly indicated," unless it is merely intended as a warning not to depend upon atropia alone or give it in poisonous doses. On the contrary, I agree with H. C. WOOD—p. 250, *op. cit.*, p. 675, *supra*—that the reported cases are sufficient to "establish the therapeutic value of atropia in opium-poisoning," and that it should almost always be employed in the advanced stages of that accident, especially when the progressive failure of the respiratory function threatens a fatal issue.

stated, in 1868, that, more than seven years before, he was induced by theoretical considerations to use hypodermic injections in which morphia and atropia were combined, and he claimed for this method not merely an increased anodyne effect, but the possibility of employing safely, or at least without great or lasting cerebral or cardiac disturbances, large doses of these narcotics.* Harley was led by his investigations to conclude that the addition of atropia increases the hypnotic and anæsthetic effects of a given quantity of opium, while it obviates the tendency to constipation and other injurious effects. He especially advised the employment of this combination in the early stages of inflammatory diseases, and in the treatment of neuralgia and insomnia. Indeed, he expressed the opinion that by this plan persons who cannot otherwise endure a dose of opium may be brought under its beneficial influence, and that morphia as a rule should not be injected alone, unless previous experience has shown that the patient will suffer no ill effects.† These results are in accordance with our knowledge of the effects upon animals of moderate doses of atropia, which appear to produce contraction of the peripheral bloodvessels, augment the arterial pressure,‡ increase the frequency and force of the heart's action,§ the peristaltic motion of the intestines,‖ and the secretion of the urine.¶ Overwhelming doses, it is true, produce opposite effects, but this should only suggest caution as to the dose employed.

Accordingly the use of atropia and morphia combined, and especially hypodermically, has during the last few years become more and more frequent in general practice,** and I

* C. E. BROWN-SÉQUARD—*Lectures on the diagnosis and treatment of functional nervous affections*, Philadelphia, 1868, p. 72: "More than seven years ago, I was led, by the knowledge of the antagonistic effects of morphia and atropine on the brain, to inject these two agents together, so as to reap the benefit of the therapeutic effects of the one added to those of the other against pain. * * * I now employ from one-half to two-thirds of a grain of the sulphate of morphia with one twenty-fifth of a grain of the sulphate of atropine." A. RUPPANER—*Hypodermic Injections*, Boston, 1865, p. 31, note—testifies to the use of this combination by Dr. BROWN-SÉQUARD at that time.

† HARLEY—pp. 300–302, *op. cit.*, p. 746, *supra*—adds to the remark referred to in the text: "To counteract those distressing and sometimes dangerous effects which follow the subcutaneous use of morphia, combination with $\frac{1}{60}$ of a grain of sulphate of atropia will usually be sufficient."

‡ The results of experiments on this subject are by no means wholly accordant, which appears to a great extent to have happened from the circumstance that sufficient care has not always been taken to discriminate between the effects of moderate and toxic doses. I am quite willing to admit that the phenomena observed by WHARTON JONES—*On the uses and action of belladonna in ophthalmic practice*, Med. Times and Gaz., 1857, Vol. I. p. 27 *et seq.*—who saw the local application of a solution of atropia to the frog's web followed by contraction of the small arteries, may be explained in part by a reflex action resulting from the local irritation, as seems to be shown by the investigations of THOMAS HAYDEN—*On poisoning with the berries of atropa belladonna*, &c., The Dublin Quarterly Jour. of Med. Sci., Vol. XXXVI, 1863, p. 51, and MEURIOT—pp. 44–45, *op. cit.*, p. 753, *supra*; and I am inclined to give full weight to the opinions of A. v. BEZOLD u. F. BLOEBAUM—*Ueber die phys. Wirkungen des schwefelsauren Atropins*, Unters. aus dem physiologischen Laboratorium in Würzburg, Theil I, Leipsic, 1867, S. 52—who concluded from their experiments that atropia diminishes and destroys the irritability of the vaso-motor nerve centres. But it nevertheless seems probable, as MEURIOT himself concludes—p. 48 *et seq.*, *op. cit.*—that the first effect even of atropia poisoning is a moderate contraction of the peripheral bloodvessels and an acceleration of the bloodstream; and this opinion is also supported by the observations of HARLEY—p. 219 *et seq.* Further support to this view is afforded by the increased arterial pressure consequent upon moderate doses. BEZOLD u. BLOEBAUM—S. 51, *op. cit.*—found that small doses of the poison increased the arterial pressure, although large doses diminished it. H. C. WOOD—*Contribution*, &c., cited p. 754, *supra*—observed this rise in pressure even after the section of the vagus. In fact, as the latter writer very clearly indicates—p. 233 *et seq.*, *op. cit.*, p. 675, *supra*—in moderate doses atropia stimulates the vaso-motor centres, while in larger doses after a time it paralyzes them. Given in appropriate doses, therefore, it seems well calculated to counteract the effects of morphia on the blood pressure and vaso-motor centres: see note †, p. 744, *supra*.

§ The action of atropia on the heart also varies with the dose. There seems to be no doubt that in poisonous doses it paralyzes the heart's action: see in support of this statement especially S. BOTKIN—*Ueber die physiologische Wirkung des schwefelsauren Atropins*, Virchow's Archiv, Bd. XXIV, 1862, S. 88; BEZOLD u. BLOEBAUM—S. 46, *op. cit.*; and MEURIOT—p. 64 *et seq.*, *op. cit.* On the other hand, moderate doses appear to increase the frequency and force of the heart's action: see BEZOLD u. BLOEBAUM—S. 33–34, *op. cit.*; MEURIOT—*loc. cit.*, note especially the sphygmographic traces published by this author; and HARLEY—p. 221, *op. cit.*

‖ As to the action upon the peristaltic movements of the intestines, BEZOLD u. BLOEBAUM—S. 65, *op. cit.*—state that by small doses the irritability of the muscular coat is diminished, by large doses paralyzed. They affirm that when they opened the abdomens of dogs or rabbits, into whose veins from a few milligrammes to a decigramme of atropia had been injected, they always observed an unwonted condition of rest in the viscera. On the other hand, MEURIOT—p. 107, *op. cit.*—testifies that when the belly, even of an animal poisoned with a large dose of atropia introduced into the stomach or rectum, is opened, the peristaltic movements of the intestines are seen to be exaggerated in a marked degree. At a subsequent period, however, he admits that if the dose be large, paralysis follows these excessive movements; and this, I suppose, explains the contrary observations of BEZOLD and BLOEBAUM, for certainly the doses they mention are for dogs and rabbits very large, and being injected directly into the veins, may even have paralyzed from the first. The investigations of P. KEUCHEL—*Das Atropin und die Hemmungsnerven*, Dorpat, 1868, S. 35 *et seq.*—seem to show that the increased peristaltic action is really due to paralysis of the inhibitory nervous apparatus of the intestines rather than to stimulation of the muscular fibres or their motor centres; but be this as it may, there seems to be little doubt as to the fact that the motion is increased in animals by moderate doses, and this accords with clinical observation on man, in whom constipation is often relieved by the action of this drug, and the constipating effect of opium generally neutralized, though it must be admitted that, as BUCHHEIM—S. 480, *op. cit.*, p. 746, *supra*—has remarked, medicinal doses seldom augment the movements of the intestinal canal sufficiently to produce diarrhœa.

¶ For the evidence on this head *vide* note †, next page.

** Among the earlier followers of BROWN-SÉQUARD in this matter I may mention R. BARTHOLOW—*Manual of hypodermic medication*, Philadelphia, 1869, p. 89 *et seq.* I am at the present time acquainted with a number of physicians who have long habitually employed the same combination.

am disposed to believe that this combination might advantageously be employed whenever hypodermic injections of morphia are indicated in the fluxes. For this purpose $\frac{1}{100}$th of a grain of sulphate of atropia with $\frac{1}{4}$th of a grain of sulphate of morphia is usually a suitable dose for adult males, and may be injected once or twice in the twenty-four hours or even oftener, as demanded by the urgency of the symptoms. It will, however, be perhaps best for the physician to keep separate solutions of the two sulphates, to be combined in various proportions in accordance as he may desire in different morbid states to produce more or less of the peculiar effects of either drug.* Nor do I doubt that a similar combination might often be administered internally with benefit in almost all the conditions in which the internal administration of morphia is indicated during the progress of dysentery or other acute fluxes.

Moreover, the action of atropia on the kidneys may perhaps be utilized in those cases of dysentery in which the secretion of urine is diminished or suppressed. It should be borne in mind that this action is probably dependent, to a great extent at least, upon the modification of the blood pressure produced by the drug, and that when this is lessened by the operation of excessive doses the secretion of the kidneys is diminished. It is useless, therefore, to attempt to produce the desired effect by increasing the quantity administered, if moderate doses fail to act. The interesting experiments of Harley relating to this subject cannot perhaps be regarded as fully establishing all the conclusions he has drawn from them, but they certainly indicate an important field of inquiry.†

The extract of *stramonium* has also been employed in dysentery; but as it has become of late exceedingly probable that the alkaloid to which this drug owes its virtues is very similar to atropia, if not identical with it, the question of its employment requires no discussion in this place.‡ Nor is there sufficient evidence in favor of the use of *dilute*

* The atropia solution may conveniently consist of one grain of the sulphate dissolved in five hundred minims (*i. e.*, one fluid ounce and twenty minims) of distilled water; the morphia solution, of eight grains of the sulphate dissolved in one fluid ounce of distilled water, which is the strength of the liquor morphiæ sulphatis of the U. S. Pharmacopœia. Five minims of the first solution will contain $\frac{1}{100}$ of a grain of sulphate of atropia, and fifteen minims of the second will contain $\frac{1}{4}$ of a grain of sulphate of morphia. The two together will make twenty minims, a very convenient quantity for a hypodermic injection. Some practitioners may prefer solutions of double this strength, to which I have no objections, provided sufficient care is taken in their preparation and use. Both solutions soon spoil in consequence of the growth of a penicilium, and should therefore not be kept for any length of time. As to the quantity of either salt that may safely be administered in this way, extraordinary differences of opinion have been expressed. Some physicians have, without hesitation, administered sulphate of atropia in doses which may well be called poisonous, if we judge from their own account of the effects produced: see on this subject, for instance, the authors cited by EULENBURG—S. 209 *et seq.*, *op. cit.*, p. 748, *supra*. The hypodermic use of morphia has, I fear, been equally abused. I am disposed to advise that, under ordinary circumstances, more than $\frac{1}{50}$ of a grain of sulphate of atropia should not be injected at once, and that the quantity used in the twenty-four hours should rarely exceed $\frac{1}{30}$ of a grain. As for the morphia, it is seldom advisable to give more than three-quarters of a grain in the twenty-four hours, and two quarter-grain doses will usually produce all the effect desirable, except in the case of those who have become habituated to its operation. But in using these drugs in the treatment of the fluxes the rule to administer no more than is imperatively demanded by the exigencies of each case should always be rigidly observed.

† HARLEY—Chap. V, p. 209 *et seq.*, *op. cit.*, p. 746, *supra*—states that atropia is freely eliminated by the kidneys. He convinced himself by placing between the eyelids a few drops of the urine of individuals who had received hypodermic injections of atropia; in 18 to 20 minutes after the injection of $\frac{1}{18}$ to $\frac{1}{30}$ of a grain of the sulphate he found this secretion would dilate the pupil: "Twelve drops of eight ounces of urine secreted during the action of the $\frac{1}{18}$ of a grain of the salt, are sufficient to dilate the human pupil from $\frac{1}{10}$ to $\frac{1}{8}$ of an inch in diameter, and maintain it thus dilated for 8 or 10 hours." Or the atropia may be separated from the urine by agitating it with chloroform, allowing the latter to evaporate spontaneously, and dissolving the residue in a few drops of water, which may be tested by placing it between the eyelids. He concludes that "the fullest medicinal doses are wholly removed by the kidneys alone," and that "belladonna indeed is, in the truest sense of the word, a diuretic, and more powerful perhaps than any other that we possess"—p. 213. According to his observations the urinary secretion in a given time is more than doubled by its action, while the specific gravity is only diminished a third; there is therefore an increase in the solid constituents eliminated, which increase, his analyses showed, was slight for the urea and chlorine, great for the phosphates and sulphates. He therefore strongly commended the use of belladonna or its alkaloid both in acute nephritis and in chronic albuminuria—p. 253 *et seq.* According to MEURIOT—p. 120, *op. cit.*, p. 753, *supra*—moderate doses of atropia increase the secretion of urine because they increase the arterial pressure; but when, in consequence of toxic doses, the arterial pressure falls, the urinary secretion diminishes or ceases. I doubt not that this explanation is correct; but if atropia is eliminated by the kidneys, as HARLEY seems to have proved, it may also exercise a directly stimulating effect on their functions. Investigations to settle this point are desirable. H. C. WOOD—p. 242, *op. cit.*, p. 675, *supra*—speaking of the action of small doses on the urinary secretion, writes: "I am confident, however, that this increase varies very much, and is not always marked," which is probably true; and I readily admit this whole question requires further careful study.

‡ That extract of stramonium has been employed in dysentery is testified by SAVIGNAC—p. 377, *op. cit.*, p. 620, *supra*, and BARBALLIER—p. 773, *op. cit.*, p. 603, *supra*. LECLERC—note ‡, p. 753, *supra*—sometimes applied it externally to the abdomen in lieu of belladonna. It enters into the compound recommended some years since by W. KERR—*On a new remedy for dysentery*, Edinburgh Med. Journal, Vol. X, Part 2, 1865, p. 1106—which contained seven ingredients, "four officinal, viz., opium, stramonium, dulcamara, digitalis; three non-officinal, sium lineare, cicuta maculata, conioselinum canadense. All are more or less narcotic; and digitalis, dulcamara, and sium lineare are also diuretic." With regard to the probable identity of daturia and atropia, see note †, p. 752, *supra*.

hydrocyanic acid,* or of the extract of *cannabis indica*,† in the treatment of the fluxes to make it important to do more than mention them here; together with morphia, chloroform and other ingredients, they are said to enter into the composition of *chlorodyne*, a nostrum which has enjoyed considerable reputation, especially in the British Empire, in the treatment of cholera and the fluxes generally.‡ This nostrum has recently been employed with alleged benefit in the diarrhœa of Cochin China by some of the French Naval surgeons.§

* This appears to have been first given in the form of cherry-laurel water, which is commended as an addition to clysters for the relief of tenesmus by NAUMANN—Bd. IV, Abth. 2, S. 91, *op. cit.*, p. 645, *supra*. J. ELLIOTSON—p. 1061, *op. cit.*, p. 267, *supra*—advised the administration of three or four drops of dilute hydrocyanic acid as a means of enabling the stomach to retain without nausea the pills of sulphate of copper and opium he employed in chronic dysentery. COPLAND—Vol. I, p. 729, *op. cit.*, p. 682, *supra*—remarks: "The prussic acid, with camphor, ipecacuanha, and mucilages, is of benefit when judiciously prescribed." VOGT—S. 187, *op. cit.*, p. 645, *supra*—refers to the use both of cherry-laurel water and hydrocyanic acid, but without praise. I am disposed to think that the dilute acid might prove occasionally useful to allay vomiting, when this symptom becomes troublesome during the progress of dysentery or other fluxes. Cyanide of potassium in the dose of $\frac{1}{12}$th to $\frac{1}{10}$th of a grain may be advantageously substituted in such cases as a more convenient equivalent.

† Cannabis indica has been but little used in the fluxes, and chiefly in combination with opium or other narcotics, as for example in chlorodyne—see next note. I know of no careful study of its peculiar effects in these diseases. As an anodyne and hypnotic it is far inferior to opium in efficacy and certainty, but has the advantage of not disordering the appetite or constipating. It may prove occasionally useful, especially in the chronic fluxes; but the very variable strength of the extracts in the market constitutes a serious objection to its use. See, particularly on the therapeutic value of this drug, FRONMÜLLER—S. 45 *et seq.*, *Klin. Studien*, cited p. 753, *supra*—who claims to have employed it in one thousand individuals suffering with various diseases—S. 61—and concludes that of all known narcotics it produces the most natural sleep without any injurious after-effects, and that it may be used in acute inflammatory disorders of every kind as well as in typhous conditions—S. 69. He admits, however, that its action is not so powerful or certain as opium.

‡ This is a proprietary medicine manufactured for one J. COLLIS BROWNE. Various formulæ supposed to approximate its composition have been published. If these can be at all relied upon the ancient superstitious veneration for the Theriaca of Andromachus is not yet dead; for it figures as an ingredient in several of these precious compounds. According to an article in the *Chemist and Druggist*, Vol. I, February, 1860, p. 115, "Chlorodyne was invented in the year '48 by Dr. Browne, whilst officiating in his medical capacity during the prevalence of cholera and diarrhœa among our troops in India, and was introduced to the notice of the faculty in this country by him as a 'combination of perchloric acid with a new alkaloid.'" In 1859 OGDEN published what purported to be an analysis of it—same Jour., Oct., 1859—but in the same Jour., Jan., 1860, he gave a somewhat modified formula. I have not seen these two articles, our library file of this journal being incomplete, and give OGDEN'S analysis from the February number cited above. Another formula was published by PETER SQUIRE—*Companion to the New Edition of the British Pharmacopœia*, 5th Ed., 1868, p. 80—who stated that it had been represented to him "as the composition of the popular medicine called chlorodyne;" and still another by EDWARD SMITH—*Pharmaceutical Journal and Transactions*, Vol. XI, 1869-70, p. 417. Others will be found in the journals. *e. g.*, in *The Doctor*, Vol. II, 1872, pp. 112 and 173; *The Druggists' Circular and Chem. Gazette*, Vol. XVII, 1873, pp. 79 and 128; and elsewhere. Among the most recent substitutes is the formula proposed by DOUNON—*op. cit.*, next note. As a matter of curiosity I give a few of the most prominent of these formulæ:

INGREDIENTS.	OGDEN.	SQUIRE.	SMITH.	DOUNON.
Chloroform	ʒvj.	ʒiv.	f ʒiv.	30 grammes.
Tincture of Capsicum	ʒss.	none.	f ʒvj.	30 grammes.
Oil of Peppermint	gtt. iij.	m. xvj.	m. viij.	30 grammes.
Muriate of Morphia	grs. viij.	grs. viij.	grs. xx.	10 grammes.
Perchloric Acid	gtt. xx.	none.	none.	30 grammes.
Scheele's Hydrocyanic Acid	gtt. xij.	none.	none.	none.
Dilute Hydrocyanic Acid	none.	ʒij.	f ʒiv.	10 grammes.
Tincture of Indian Hemp	ʒj.	none.	none.	20 grammes.
Theriaca, (Anglice, Treacle)	ʒj.	ʒiv.	f ʒiv.	none.
Ether	none.	ʒj.	f ʒij.	20 grammes.
Alcohol, (dilute)	none.	ʒiv.	none.	none.
Extract of Glycyrrhiza	none.	ʒiiss.	none.	none.
Syrup	none.	ʒxviiss.	none.	none.
Mixture of Gum Arabic	none.	none.	f ʒj.	none.
Pure Molasses	none.	none.	none.	200 grammes.

I note that the first and last of these formulæ contain Indian hemp, while the others do not. In the two formulæ cited in *The Doctor*, tincture of lobelia is substituted for the hemp. The first of the formulæ cited in *The Druggists' Circular* contains Indian hemp, the second does not. All the English formulæ cited contain Theriaca, which in some of them is written treacle—see note ‖, p. 729, *supra*; in *The Druggists' Circular*, by a blunder which appears to result from ignorance, molasses is written instead, and DOUNON falls into the same mistake. I have not thought it worth while to make a list of all the numerous articles on the subject of chlorodyne which have appeared in the medical journals. A number of them will be found in the *Pharmaceutical Journal and Transactions*, especially in Vol. XI, 1869-70, *passim*. Several fatal cases resulting from its reckless use are reported by A. S. TAYLOR—*On Poisons*, &c., 3d Ed., London, 1875, Chap. 56, p. 568.

§ Chlorodyne appears to have been brought into use for this purpose by DOUNON—*Guide pratique pour le traitement par la chlorodyne de la diarrhée de Cochinchine et des affections parasitaires du tube digestif*, Nov., 1877, 1re Éd., Dec., 1877, 2e Éd.; I have not seen the paper, and cite from the critical review in the Archives de Méd. Navale, T. XXIX, 1878, p. 360. The connection between the pathology and treatment seems here not inappropriate: undemonstrated suppositions in the first, and a secret nostrum for the second. The author is quite sure that the Cochin China diarrhœa is due to NORMAND'S *anguillula*—see p. 372, *supra*—but he seems to have been himself a little ashamed of his English chlorodyne, for he speedily substituted for it an imitation chlorodyne prepared by a Toulon pharmacist, and then one devised by himself: see p. 370 *et seq.*, of the review, and p. 31 of CHASTANG'S paper, cited *infra*, also note †, *supra*, for the formula of DOUNON'S chlorodyne. E. CHASTANG—*Diarrhée dite de Cochinchine, quelques notes sur son origine parasitaire et son traitement par la chlorodyne*, same Jour., T. XXX, p. 29—denies that the anguillula is constantly present in this form of flux, which he does not think is caused by it. He was induced by DOUNON'S publication to try the English chlorodyne in a number of cases, and found, as might have been expected from its probable composition, that, although it generally diminished the number of stools, it did not cure, but sometimes aggravated the disease; and that in chronic cases relapses speedily followed the subsidence of the first impression of the English nostrum—p. 37. I may add in this place that since p. 372, *supra*, was stereotyped, I have read the paper of BAVAY—*Note sur l'anguillule intestinale*, same Jour., T. XXVIII, 1877, p. 64—which at that time I had not received, and several other essays on the same subject, viz., CHAUVIN—*L'anguillule stercorale dans la dysenterie des*

But all the objections to secret remedies, as a class, apply to this preparation, and all the criticisms that sound logic has offered with regard to ancient polypharmacy may be urged against the various formulæ which have been devised to imitate it; any serious discussion of its supposed virtues would be out of place in these pages.

More than twenty years ago Lownds and Stovell drew attention to the usefulness of *chloroform* in relieving the tenesmus of dysentery. They gave it internally in the dose of twenty minims. Morehead states that he has used it in several cases, and admits that its power of allaying the pain consequent on intestinal spasm is undoubted; but remarks that when repeated several times it is apt to create gastric irritation, indicated by a sense of heat at the epigastrium and a florid tongue, and expresses the opinion that it should therefore only be occasionally used.* Barrallier declares that chloroform can rarely be useful in dysentery because it lowers the temperature and augments the number of stools;† but he gives no authority for either statement. The first is probably based upon the well known fact that in profound chloroform-narcosis the animal temperature is lowered;‡ but I know of no evidence to show that any such effect occurs after the internal administration of suitable medicinal doses. I know not what observations may have suggested the second statement, which is rendered improbable by the well known action of the drug when administered to relieve the painful cramps that so often accompany acute intestinal catarrhs. In fact chloroform enters into the composition of several of the diarrhœa mixtures popular in this country, and while the vulgar practice of habitually resorting to preparations of this class deserves censure, it is exceedingly probable that the addition of chloroform increases their efficiency and diminishes the frequency of injurious after-effects.§

Antilles, same Jour., T. XXIX, 1878, p. 154; NORMAND—*Du rôle étiologique de l'anguillule dans la diarrhée de Cochinchine*, same Jour., T. XXX, 1878, p. 214—who still maintains his theory; and the thesis of P. A. ROUX—*De l'anguillule stercorale et de son rôle dans l'étiologie de la diarrhée de Cochinchine*, Paris Thesis, No. 222, 1877—who hesitates to accept it, and calls for new researches. Several other essays are cited in the review referred to above, which I have not seen. The evidence, so far as it has come into my possession, strengthens the opinion expressed on pp. 372–3, *supra*, as to the significance of this parasite, and I note that the same view is taken in the review just mentioned.

* The volume of the *Transactions of the Medical and Physical Society of Bombay*, No. 3, for the years 1855–6, which contains the observations of LOWNDS and STOVELL, is unfortunately not in our library; I cite from MOREHEAD—p. 304, *op. cit.*, p. 657, *supra*—who concludes that "chloroform should, therefore, be only used occasionally, to relieve tenesmus or other symptoms of spasm of the muscular fibre of the intestine, when urgent;" but suggests in a foot note that the vapor of chloroform, introduced into the rectum, under the circumstances in which opiate enemata are usually employed, appears to be worthy of trial. G. MEAD—*Chloric ether; its properties and uses*, Association Med. Jour., 1854, Vol. II, p. 819 *et seq.*—had previously employed the so-called chloric ether in choleraic and other forms of diarrhœa, and in cholera.

† BARRALLIER—p. 774, *op. cit.*, p. 603, *supra:* "Le chloroforme est rarement utile dans la dysenterie, car il abaisse la calorification et augmente le nombre des évacuations."

‡ The principal authorities for this statement are DUMÉRIL et DEMARQUAY—*Rech. exp. sur les modifications imprimées à la température animale par l'éther et par le chloroforme*, &c., Archives Gén. de Méd., T. XVI, 1848, p. 192 *et seq.*, and J. SCHEINESSON—*Unters. über den Einfluss des Chloroforms auf die Wärmeverhältnisse des thierischen Organismus und den Blutkreislauf*, Inaug. Diss., Dorpat, 1868. The observations of both refer to the chloroform-narcosis produced by inhalation, carried in some of the experiments to a fatal issue; and the more elaborate studies described in the latter paper seem to show that the lowering of temperature depends on a diminished heat-production, resulting in part from the retarded circulation, in part from diminished tissue-metamorphosis—S. 82.

§ Diarrhœa mixtures containing chloroform have been used in the United States for more than twenty years. I well remember one containing, besides chloroform, the tinctures of opium, camphor, capsicum, kino, &c., which was in use in the medical wards of Blockley Almshouse as long ago as 1854, under the name of "mixture of seven," from the number of its ingredients. One of the most popular preparations of the sort is that proposed by Dr. E. R. SQUIBB—*Advice upon epidemic cholera*. New York, 1866—and designated "compound tincture of opium, or diarrhœa mixture." Proposed for use during the prevalence of epidemic cholera, it has since been extensively employed under other circumstances. It "is composed of tincture of opium, spirit of camphor, and tincture of capsicum, each one fluidounce, purified chloroform, three fluiddrachms, and a sufficient quantity of stronger alcohol to make the whole measure five fluidounces." The dose for persons over 18 years of age is a teaspoonful. The directions are that, "in time of epidemic cholera or diarrhœa when any person has two movements of the bowels more than natural within the 24 hours, the second one should be followed by a dose of this mixture, the dose to be repeated after every movement that follows. If the movements increase in frequency or in copiousness after the second dose of the medicine has been taken, a physician should be sent for at once, and a double dose be taken after each movement until he arrives. Immediately after taking the first dose, the person should go to bed, and remain there for 12 hours after the diarrhœa has entirely ceased." In the same pamphlet is reprinted the address to the public of the Metropolitan Board of Health of New York on the prevention of cholera, a part of which advises in cases of diarrhœa that "in the absence of a physician the adult can take ten drops of laudanum and ten drops of spirits of camphor," and that "these drops may be repeated every twenty minutes so long as diarrhœa or pain or vomiting continues." The attentive reader will readily understand how easy it would be to cite authorities either in favor of such a plan of treatment or against it. I believe the weight of the evidence is on the latter side. I cannot agree with my esteemed friend Dr. SQUIBB that whenever a person has two movements of the bowels more than natural within twenty-four hours he ought necessarily to take the diarrhœa mixture described above, or any other preparation containing opium. Still less do I think this treatment is wise during the epidemic prevalence of cholera, of diarrhœa or of dysentery, without the preliminary use of evacuants, or without the precautions insisted upon when opium was under discussion. At the same time, for those who insist upon resorting to opiates under these circumstances, I think Dr. SQUIBB'S preparation better than laudanum alone, though I would fain omit from it both the capsicum and the camphor.

In dysentery, however, the effects of chloroform have not been sufficiently studied to warrant the expression of an opinion as to the extent of its usefulness. It is probable that, like atropia, the greatest benefits are to be expected from it when it is given in combination with morphia. Claude Bernard has shown that animals that have previously received small doses of morphia come much more readily under the influence of chloroform, smaller doses of which are sufficient to produce complete anæsthesia. This observation has already been utilized for surgery and obstetrics. It has been found possible, in the case of individuals who have previously received hypodermic injections of morphia, to produce complete analgesia without carrying the inhalation of the vapor to the point of producing unconsciousness;* but so far as I know no careful study of the combined effect of the internal administration of chloroform and morphia has as yet been undertaken.

If it should prove possible by this combination to relieve urgent pain and intestinal spasm with a smaller quantity of morphia than would otherwise be needed, it would be a valuable addition to our resources, even if the relief thus obtained were no more complete and certain than can be obtained by morphia alone. Moreover, the circumstance observed by Rutherford and Vignal, that chloroform is an energetic stimulant of the hepatic secretion is of precious significance in this connection, and indicates the propriety of combining chloroform with the morphia administered in acholic conditions.† The internal use of chloroform in connection with morphia for the relief of tenesmus and other forms of painful intestinal spasm seems, therefore, well worthy careful trial. The only probable difficulty that suggests itself is the irritability of the stomach in certain groups of cases. Further experience is required to show how far this constitutes an actual objection to its use, as well as to determine the question of dose. For preliminary experiments in this direction I should not hesitate, when pain is great, to exceed the dose employed by Lownds and Stovell, and to repeat it after an hour's interval, if relief were not afforded.‡

Cameron directed attention, in the year 1870, to the employment of *hydrate of chloral* in acute gastro-enteritis by the statement that he had cured two severe cases, each with a single dose.§ In 1875 Prince suggested the use of the same drug as a means of aborting acute dysentery. He gave it in sufficient dose to produce sleep; on an average thirty grains, with an ounce or two of sulphate of magnesia and enough water to make a solution. A dose of salts so small that it fails to secure a free watery discharge he regarded as worse than useless, and too small a dose of chloral as apt to produce troublesome delirium. I do not doubt that this treatment proved, in the cases referred to, as efficient as claimed; but there is nothing in the paper to show that these cases were other than mild catarrhal forms;

* CLAUDE BERNARD—Leçon 8, p. 225 *et seq.*, *op. cit.*, p. 746, *supra*. In this lecture the reader will find references to the earlier application of the method to surgery and obstetrics. In cases of labor, GUIBERT injected 1 to 2 centigrammes (about ½ to ¼ of a grain) of morphia subcutaneously, and then found that the inhalation of extremely small quantities of chloroform vapor from time to time enabled him to maintain a state of analgesia for several hours, without even carrying the chloroform to the extent of producing insensibility. Equally brilliant results in connection with surgical operations are referred to, and BERNARD declares that he knows of no more efficient means of securing immobility in animals during vivisections.

† RUTHERFORD and VIGNAL—Vol. XI, p. 62, *op. cit.*, p. 277, *supra*: "In two of our earlier experiments we administered chloroform during the preliminary operation, but the stimulation of the liver produced thereby was so remarkable, that the animals were rendered useless for further experimentation," (*i. e.*, for experiments to ascertain the action of other cholagogues.)

‡ In hepatic and nephritic colic I have repeatedly given 30 minims of chloroform at a dose, and sometimes had to give a second dose before the pain was relieved. In the case of a gentleman suffering from nephritic colic, to whom several half-grain doses of morphia had been administered with the effect of producing great cerebral excitement without apparent relief from pain, I saw a single such dose followed by immediate analgesia, and shortly after by a prolonged and refreshing sleep, during which the calculus descended into the bladder. I have usually, however, found much smaller doses sufficient for the relief of the painful cramps of intestinal catarrh. In none of the cases in which I have used chloroform has it appeared to irritate the stomach, but I have never used it in acute dysentery, and can therefore contribute no personal experience to the question of its employment in that disease.

§ EVAN CAMERON—*Notes of two cases of severe diarrhœa cured by single doses of chloral hydrate*, The Lancet, 1870, Vol. II, p. 602. In both these patients (males) there was vomiting as well as purging, and they appear to have been what we would call in this country cases of cholera morbus. The first received 20, the second 15 grains only. I note that each received as a part of the same dose 15 minims of chloric ether, the chloroform contained in which was no doubt also useful. It is claimed that in both cases the vomiting and purging ceased immediately after taking the dose.

and many additional observations will be required before we can accept the view that chloral acts in dysentery as an antiseptic, destroying that quality of the inflammation by which it extends along the mucous membrane and becomes infectious.

Among the objections to this use of chloral is the probability that it may irritate the stomach. Prince encountered this difficulty so frequently that he advises the physician to have always a second dose ready to administer if the first is rejected. He found, however, that a previous subcutaneous injection of morphia was an efficient aid in rendering the stomach tolerant. Perhaps, however, his mixture of the chloral with Epsom salt, making a bulky and nauseous dose, was greatly to blame for this result, and the trouble would have been less had the medicines been administered separately.* This suspicion is strengthened by the circumstance that Lambert, who gave chloral in dysentery, alternating with other remedies, does not appear to have found it disturb the stomach.†

Liebreich himself has counselled against administering chloral to patients suffering with intestinal ulceration, except very much diluted with mucilaginous fluids;‡ and it is probable that this precaution is necessary; but in weak solutions it has been applied externally to chronic ulcers with apparent benefit, and this circumstance suggested to Newell the use of such solutions as enemata in acute dysentery. The beneficial results he obtained led to a trial of the method by Whitaker, who is said to have found it capable of aborting the disease in a few hours.§ Similar enemata have been employed with benefit by Tyson for the relief of the tenesmus accompanying certain summer fluxes of children.‖ These observations seem to warrant further experiments with chloral hydrate in the treatment of the fluxes, but can hardly be regarded as representing an experience sufficiently extensive to fix satisfactorily the circumstances in which it may be advantageously employed.

A few years since Salvatore Caro (1869) suggested the treatment of summer fluxes, especially in the case of children, with *bromide of potassium.*¶ He was careful to use

* DAVID PRINCE, of Jacksonville, Ill.—*op. cit.*, p. 748, *supra*. How difficult he found it to give this mixture may be inferred from the following passage: "The administration of salts and chloral should be done by the practitioner, otherwise there can be no assurance that it will all be taken. The unpleasant taste offends the patient, and the bulk seems enormous to friends, and it is likely to be concluded that half the dose is enough, or if the first dose is thrown up, that the medicine does not agree, and the physician is charged with a blunder. The prescription method is not therefore as reliable as the personal dosing by the physician." This paper was read before the Morgan County Medical Society, August 12, 1875.

† S. H. LAMBERT, of Ogden, Ind.—*Hydrate of chloral in dysentery*, The Clinic, Sept. 11, 1875, p. 126—began his treatment by giving "a good dose" (gtt iv.) of fluid extract of aconite, which he followed by a dessertspoonful every two hours of a solution of two scruples of hydrate of chloral in two ounces of sweetened water. On the alternate hours he gave powders containing subnitrate of bismuth, tannic acid and ipecacuanha; and on the third day stopped the chloral and substituted a chalk mixture alternating with powders of bismuth and pepsin. One case is reported in detail, but the language used implies that it was not the only one: "We are having an epidemic here of the above named disease, and having treated it successfully with hydrate of chloral, is my excuse for reporting the following case."

‡ I cite from a review of the third edition of LIEBREICH'S work—*Das Chloral Hydrat;* [our library has nothing later than the 2d Ed., Berlin, 1869, which does not contain the passage in question,] in the Gazette Médicale de Strasbourg, No. 14, 1871, p. 171. Among the contraindications to the use of chloral laid down by LIEBREICH, the first is said to be "extensive destructive processes of the mucous membrane of the primæ viæ; in these cases, if the medicine is indicated by other reasons, it ought to be very much diluted with mucilaginous substances, or still better given in enema."

§ W. L. NEWELL, of Millville, N. J.—*Chloral in dysentery*, Letter dated June 25, 1878, to the Editor, Philadelphia Med. Times, Vol. VIII, 1878, p. 499. For a child aged 11 years he used an injection of 5 grains of chloral hydrate dissolved in two fluidounces of starch gruel. This injection was repeated, "four being given in all." He adds: "The case seemed so satisfactory that I mentioned it to my confrère, Dr. J. S. Whitaker, who has pursued the same treatment with the most happy results in every case, aborting the disease within a few hours. I may mention that he used ten grains instead of five with a lady aged 25, who had twenty or thirty calls in twenty-four hours, with complete repose for eight consecutive hours, with permanent abatement of all other symptoms, without other treatment. The number of aggravated cases of dysentery we have treated with the chloral hyd. warrants us in the assertion that if early and properly used it is *almost* a specific."

‖ J. L. TYSON—*Chloral hydrate and oxide of zinc in acute intestinal diseases of childhood*, same Vol., p. 581—made his enemata by dissolving thirty grains of chloral hydrate in two ounces of starch-water, and injected from a teaspoonful to a teaspoonful and a half once or twice in the twenty-four hours: (this was not a very weak solution, but no harm appears to have resulted from this circumstance.) His object seems to have been merely the relief of the tenesmus, and oxide of zinc was at the same time given internally. Two typographical errors in this article are corrected in the same volume—p. 624.

¶ SALVATORE CARO—*The treatment of summer complaints by the bromide of potassium*, The Med. Record, Vol. IV, 1869-70, p. 195: this paper was read before the Medical Society of the County of New York, June 7, 1869; an abstract of the discussion that followed will be found in the New York Med. Jour., Vol. IX, 1869, p. 527—reported 163 cases, most of them children. Of these but three died, "and the fatal result in these was due not to the bowel complaint, but to other causes"—p. 200. I note in this paper the following statement with regard to cholera infantum: "By microscopical examination I have found in the vomited matter only undigested food, in different stages of disintegration, and small particles of the mucous membrane of the stomach. The fæces in the beginning of the affection are like broken-down and half-digested particles of food. When the stools have turned green, they contain decomposed blood and bile; when white, large quantities of mucous membrane, and even matter; and when red, blood"—p. 196. I know not what the author has mistaken for "mucous membrane" in these observations, and I must leave him to reconcile as best he can the presence of blood and pus in the stools, to

moderate doses, admitting that with large ones he did not obtain satisfactory results. Bailey has reported the successful trial of this method in a number of cases, and Williams wrote that he shared the confidence of Caro in the value of this mode of treatment; but it appears that, after a short trial of the bromide by itself, both these physicians were led to use it combined with opiates and other remedies.* Caro himself went so far as to claim specific virtues for his plan of treatment, a claim which has also been made by some of those who have advocated the hydrate of chloral. Into such exaggerations practitioners are only too prone to fall after brief trial of new methods; and these exaggerations, the result of generalization upon insufficient premises, are, as might be expected, not always in the same direction. Thus, only six months before Caro read his paper in New York, Moutard-Martin, communicating his experience with bromide of potassium in the diseases of infants to the Academy of Medicine in Paris, expressed the opinion that the existence of diarrhœa contraindicated its employment.†

It appears much less probable that either of these extreme views is correct than that further observation will indicate some definite field of usefulness for the bromides in the treatment of the fluxes. They may be hoped to prove beneficial particularly in simple diarrhœas due to mere irritation, or mild catarrhal inflammation of the intestinal mucous membrane complicated with nervous excitement or irritability. Such are often the diarrhœas of teething infants, for which I have myself prescribed the bromide of potassium with advantage in a number of instances, and it is not improbable that there are many other varieties of flux in which the action of this drug in diminishing nervous excitement and reflex activity would exercise a favorable influence upon the progress of the complaint; but no evidence has yet been brought forward that warrants the expectation of any curative influence in violent acute inflammations or in the diphtheritic cases.‡

ASTRINGENT AND DRYING REMEDIES.—Medicines coming under these heads were freely employed by the Greek physicians in the treatment of the fluxes. Cælius Aurelianus testified that Diocles combined galls with the opium he gave in dysentery, and criticised Erasistratus because he relied solely upon astringents in that disease when so many patients require laxative treatment.§ By the time of Galen a great variety of medicaments possessing, or supposed to possess, astringent or drying virtues had come into use. In his writings the more potent styptic and caustic mineral substances, such as alum, the scales struck off by the smith in hammering copper, burnt copper, sandarach, orpiment and other forms of arsenic,

---

which he himself testifies, with his speculation that the disease is not inflammatory, but "arises from an over-excitement of the nervous and vascular systems, and that therefore the bromide of potassium affects it, and acts as a sure cure"—p. 200. But notwithstanding this fantastic speculation, and the wild assertion that "the bromide of potassium is an invaluable remedy, nay, a specific in summer-complaints," the author must be credited with having made a suggestion of practical value, by drawing attention to the use of this drug in the fluxes. He usually gave to children 10 to 30 drops, every hour or two, of a mixture containing 10 to 30 grains of the bromide in an ounce of mucilage or orange-flower water.

* F. K. BAILEY, of Knoxville, Tenn.—*The Bromides*, The Chicago Med. Examiner, Vol. XI, 1870, p. 19, and *Bromide of potassium*, The Med. and Surg. Reporter, Vol. XXXI, 1874, p. 201. In the latter paper he states that he now generally combines the bromide with "some aromatic and an opiate." F. G. WILLIAMS—Chicago Med. Examiner, Vol. XII, 1871, p. 346—writes from Watertown, Wis., April 11, 1871: "After a faithful trial, during two seasons in which there has been a great prevalence of diarrhœa and dysentery, I am almost as confident of the value of the treatment as is Dr. Caro." He adds that he no longer uses it alone, but gives it combined with rhubarb, morphia, &c. To these commendations I may add the testimony of C. G. POLK—*Bromide of potassium and the diseases of dentition*, The Med. and Surg. Reporter, Vol. XXIX, 1873, p. 61.

† E. MOUTARD-MARTIN—*Note sur quelques applications nouvelles du bromure de potassium à la médecine des petits enfants*, Bull. Gén. de Thér., T. LXXVII, 1869, p. 391. This paper was read to the Imperial Academy of Medicine, December 1, 1868. The author strongly commends the bromide in the insomnia of infants, and for the relief of certain accidents of dentition and various nervous disturbances, but boldly adds: "On ne doit pas administrer le bromure de potassium aux petits enfants qui ont la diarrhée."

‡ I have not overlooked the advantages claimed to have been obtained by JAMES BEGBIE—*Note on the use of the bromide of potassium in cholera*, The Lancet, 1866, Vol. II, p. 664—from half-drachm doses of bromide of potassium, given every hour or every half hour, in Asiatic cholera: "Let it be used early in the disease," he writes, "It will arrest the cramps—almost the only pain the patient suffers; it will calm the tossings on the sick-bed as few other remedies can." One of the patients, a woman, took two ounces of the bromide of potassium in twenty-four hours, and recovered. Others treated in the same way died. The evidence brought forward does not satisfy me that the progress of the cases was modified by the treatment.

§ CÆLIUS AURELIANUS—*loc. cit.*, p. 735, *supra*. On the following page he adds: "Erasistratus secundo libro de ventre plurima recte componens, solis utitur constrictivis, cum sint plurimi dysenterici laxatione indigentes."

quick-lime and the like, are for the most part directed to be administered in the fluxes only in the form of enemata.* But he lauded whey in which pieces of red-hot iron had been extinguished, for the purpose of giving it astringent virtues, as one of the very best remedies in these disorders.† So, too, he frequently employed by the mouth a variety of prepared earths, named after the countries that furnished them, especially those from Lemnos, Samos and Armenia, which were not merely regarded as possessed of drying powers that might safely be employed in checking the alvine fluxes, since they were free from any acrid properties, but were believed to favor the cicatrization of ulcers, and hence were commended as applications to external sores as well as in the treatment of ulcerative dysentery.‡ He also approved the use of a number of substances, derived from the animal world, which owed their virtues chiefly to their mineral ingredients; among these were the burnt horns of deer and goats, and the burnt shells of oysters, or snails and crabs burnt whole, to all of which he attributed a certain vis exiccatoria.§

Still more numerous were the vegetable astringents employed by Galen in the treatment of the fluxes: among these were the white and Egyptian thorn, the plantain, the flowers of the wild pomegranate, the common bramble, oak-bark and acorns, galls, cistus and hypocistis, green mulberries, the water-lily, Pontic rhubarb, dried roses, the rind of the pomegranate and many others.‖ Some of these he regarded as desiccative or refrigerant, or both, as well as astringent; others he believed to possess special virtues in healing ulcers; some he especially commended for use in dysentery, others in the cœliac affection also, or in the fluxes generally. Mixed with anodynes, aromatics, etc., these mineral or vegetable restraining remedies figure in the majority of the formulæ for internal use in the fluxes

* Some account of the enemata used by the Greek physicians will be given further on.

† GALEN—*loc. cit.*, p. 664, *supra*. In this passage he teaches that if drying properties be bestowed upon whey, it is one of the best remedies for dysentery and all acrid fluxes. For this purpose red-hot flints may be extinguished in it, but even better results are obtained by treating it in the same way by red-hot iron cylinders, "for iron as has been shown possesses also astringent virtues."

‡ For GALEN'S description of these earths and their properties, see especially *De simp. med. temp. ac fac.*, Lib. IX, Cap. 1, [Ed. Kühn, XII, 165 *et seq.*] As to the drying powers assigned to them we read, "desiccandi namque vim terra quævis possidet"—p. 177—with the explanation that since such bodies are by nature dry, and devoid of any mixture of igneous substance, they are almost devoid of irritating properties (minime mordax) especially if washed. Washing till all soluble matters were removed was indeed the general mode of preparation—p. 178. The *Lemnian earth*, of which a favorite variety was known as the Lemnia rubrica or sigillum Lemnium, because the cakes put into the market were marked with the sacred seal of Diana—p. 169—had especially the reputation of healing old and obstinate ulcers if applied to their surface—p. 174. The *Samian earth* was said to be advantageous to dysenteric ulcers if used by the mouth or rectum before they become putrid, and indeed even then sometimes proved beneficial—p. 179. The *Armenian earth*, long afterwards used in medicine under the name of Armenian bole, was useful not merely in dysentery and diarrhœa, but in spitting of blood and in catarrhal affections generally—p. 190. These earths figure in many of the formulæ for internal remedies employed in the treatment of dysentery and other fluxes which have been preserved by GALEN: see, for example, *De comp. med. secundum locos*, Lib. VII, Cap. 4, [Ed. Kühn, XIII, 73 *et seq.*]

§ For the *burnt horns* referred to in the text, see *De simp. med. temp. ac fac.*, Lib. XI, Cap. 1, [Ed. Kühn, XII, 334 *et seq.*] The burnt horns of deer (in modern materia medica calcined hartshorn) are said to cure dysentery and the cœliac affection, "est enim scilicet omnium talium vis exiccatoria." *Burnt oyster shells* are reputed to be useful in chronic fluxes—p. 346. *Snails burnt with their shells* are wonderfully advantageous in dysentery if mixed with galls and white pepper—p. 355—and the *ashes of river crabs* are likewise exiccating, although they have a more remarkable use in the treatment of the bites of mad dogs—p. 356. The *dung of dogs fed on bones*, a substance rich in lime salts, was also a favorite remedy; it was used with milk: see note ‡, p. 664, *supra*.

‖ See *De simp. med. temp. ac fac.*, Lib. VI, [Ed. Kühn, XI, 819 *et seq.*,] for accounts of the *acantha alba* or *spina alba*, white thorn, the root of which is said to be desiccative and moderately astringent, and therefore advantageous to cœliacs; the *acantha Ægyptia*, Egyptian thorn, is said to possess similar properties but in a higher degree; both its seeds and roots were used. The *plantain* or *Arnoglossum* is astringent, desiccative and refrigerant, useful in all fluxes, in rebellious ulcers as well as in putrid conditions, therefore especially in dysentery; all parts of the plants were used—p. 838. *Balaustium*, the flowers of the wild pomegranate, possessed similar properties, and is credited with speedily healing ulcers; this medicine is so useful in dysentery and alvine fluxes that there is no physician who has written on the treatment of these diseases who does not use them—p. 847. All parts of the *rubus* or *bramble* are decidedly astringent, and may be used in dysentery or other profluvia—p. 848. So likewise all parts of the *oak*, but particularly its *bark* and *acorns*, possess astringent qualities, and, especially in decoction, may be used in dysentery and chronic fluxes—p. 866. In the same treatise, Lib. VII, [Ed. Kühn, XII, p. 24 *et seq.*,] *galls* are described as still more astringent, and also to some degree drying and refrigerant. They dry up and restrain fluxes of all kinds. The *cistus* or *rock rose* is astringent in all its parts; its flowers are especially efficacious, if drunk with wine, in dysentery, and cure other fluxes. Moreover, *hypocistis*, the juice of a parasitic plant that grows under the roots of the cistus, (perhaps also the parasite itself,) is still more astringent than cistus flowers, and is a very efficacious remedy in the cœliac affection, dysentery and all fluxes—p. 27. Other drugs of similar properties commended in these disorders are a decoction of the wood of the *lotus-tree*—p. 65; unripe mulberries—p. 78; and in Lib. VIII, same Vol., p. 86, *nymphæa*, the water-lily; *rheum Ponticum*—p. 112; *dried roses*—p. 114; and the *pomegranate, malum granatum* or *malum Punicum*—p. 115. These are only a part of the articles of this class enumerated in the treatise cited. The English reader will find pretty satisfactory accounts of all I have named, and many others, in the third volume of Dr. ADAMS'S translation of PAULUS ÆGINETA, cited p. 624, *supra*. These vegetable astringents figure liberally in the formulæ referred to at the close of note ‡, *supra*. I may also draw attention here to a passage in the treatise cited in the present note, Lib. V, Cap. 15, [Ed. Kühn, XI, 756,] in which GALEN singles out galls, the seeds of the acantha Ægyptia and the dried rind of the pomegranate as endowed with the power of inducing ulcers to cicatrize.

which Galen has preserved. With but little change they were employed for the same purpose by all the later Greeks, as well as by the Arabian physicians, as may be seen in the writings of Alexander of Tralles, Ætius, Paulus Ægineta, Rhazes, Haly-Abbas and Avicenna.* According to Harles, some of them even went so far as to administer by the mouth quick-lime, burnt alum, and preparations of copper and arsenic, which their more cautious predecessors had used only in clysters.† Indeed, such prominence was given by the Greek and Arabian writers to the use of astringents and opiates in dysentery that later physicians, who fell into the practical error of resorting to them as the sole remedies in that disease, not unfrequently believed that they were faithfully following the ancient practice.‡

Yet already both Hippocrates and Galen had gone to the extent of exaggeration in their representation of the dangers to be feared from suddenly suppressing the alvine fluxes, and the celebrated methodist Philumenus had strongly advised that astringents should be avoided in the earlier stages of such disorders, although he claimed for them curative virtues when used later in the disease, if the discharges continued after evacuants have been fairly tried. Avicenna, too, insisted that astringents should not be resorted to at the beginning of the fluxes, though he gave them freely enough in the later stages.§

These views, which probably represented the practice of the best physicians of antiquity, were faithfully taught by the leading writers on dysentery of the fifteenth, sixteenth and seventeenth centuries. Savonarola laid it down as a general rule that astringents should not be employed in acute dysentery until after the tenth or twelfth day of the disease; Nicolaus Piso declared that astringents prematurely employed in this disorder prevent the evacuation of the morbid humors, and sometimes augment the fever and inflammation as well as make the ulcers worse; Fabricius Hildanus advised that astringents should not be given until after the fourth or fifth day from the beginning of the disease, when the fever

* ALEXANDER OF TRALLES—Lib. VIII, Cap. 8 and 9, p. 445 *et seq.*, *op. cit.*, p. 624, *supra*. ÆTIUS—Tetrab. III, Serm. 1, Cap. 35, p. 586, *op. cit.*, p. 656, *supra*—preserves the teachings of PHILUMENUS on the treatment of the alvine fluxes: note the astringents for internal use enumerated in the latter part of the chapter; those advised for the cœliac affection by ARCHIGENES will be found in Cap. 37, pp. 591–2. See also, for those commended in dysentery, Cap. 45, pp. 606–7, and the remarkable classification in Cap. 47, p. 609, which contains a list of simples useful in dysentery; under the head of astringents (quæ vero adstringunt) are found many of the vegetable astringents enumerated by GALEN, together with two kinds of earth, the *Lemnia sphragis* (described by GALEN in the chapter on earths, cited in note ‡, last page) and *minium Sinopicum*, probably a red earth from Sinope: see in BAILEY'S Ed. of the *Lexicon* of FACCIOLATI and FORCELLINI, London, 1828, Vol. II, pp. 563 and 566, the words *Sinopicus* and *Sinopis*, where Sinopicum minium is explained to be the terra Pontica or rubrica Pontica of Sinope. See also, in Vol. I, p. 1195, the word *Minium*, which is sometimes interpreted red-lead, sometimes vermilion, sometimes, however, as explained above: "Si quando usum minii legas in medicina, ut apud *Cels.* l. 4. c. 15. *sub fin.* l. 5. c. 19. n. 25. et lib. 6. c. 6. num. 22. terram Lemniam, vel synopicam rubricam interpretantur." The various burnt shells and horns, on the other hand, come under the head of drying remedies, (resiccat.) See also the list of compound remedies to be administered by the mouth in dysentery, Cap. 48, p. 610 *et seq.*, and the treatment advised for lientery in the latter part of Cap. 51, pp. 618–19. PAULUS ÆGINETA—Vol. cited last note, *passim;* also Lib. III, Cap. 40 and 41, Vol. I, p. 520 *et seq.* RHAZES—*loc. cit.*, p. 680, *supra;* also *Ad Mansor de re med.*, Lib. IX, Cap. 72, pp. 257–8. HALY-ABBAS—*Practica*, Cap. 22, fol. 246, Ed. cited p. 678, *supra;* and AVICENNA—*loc. cit.*, p. 704, *supra*. I may add that CELSUS—*loc. cit*, p. 733, *supra*—was less explicit as to the astringents to be used internally, though he advises that the patient should "take those foods and drinks which have a tendency to bind the bowels." The only astringents he mentions for internal use are cinquefoil and purslain, (portulaca.)

† C. F. HARLES—*De dysenteriæ antiquitatibus*, Opera Minora Academica, T. I, Leipsic, 1815, p. 179: "Et ulceris putatitii a septica mortificatione arcendi et escharæ cicatricisque producendæ causa externa per clysmata applicatione, interdum tamen per os quoque, æque audaci ac inepto nefandoque modo administrarunt calcem vivam, viride æris, alumen ustum, immo adeo auripigmentum, sandaracham (risigallum), et ipsum arsenicum album (a serioribus tantum Græcis, magisque adhuc ab Arabibus in usum vocatum)." I note that this author speaks on the same page of "minium, jam a CELSO memoratum, et alia saturnina," but we have seen—note *, *supra*—that the minium, which, moreover, CELSUS used only in clysters, was probably not a preparation of lead, but the red earth of Lemnos or Sinope.

‡ Note the pains which ACKERMANN—Lib. II. Cap. 2, p. 131 *et seq.*, *op. cit.*, p. 620, *supra*—takes to refute this error, beginning, "Haud recte autem sibi sapiunt medicinæ professores plurimi, qui solis restringentibus talibusque medicinis, quæ ulcera glutinant, dysenteriæ sanationem a veteribus tentatam esse existimant."

§ HIPPOCRATES—*De victus ratione in morb. acut.*, Append., § 12, [Ed. Littré, II, 469.]—enumerates the evil consequences of suddenly checking a dysentery, in a passage which ADAMS translates—Vol. I, p. 325, *op. cit.*, p. 608, *supra*—"A dysentery, when stopped, will give rise to an aposteme, or tumour, if it do not terminate in fevers with sweats, or with thick and white urine, or in a tertian fever, or the pain fix upon a varix, or the testicle, or on the hip-joints." GALEN, in his commentary on this passage—*Comm. IV*, § 71, [Ed. Kühn, XV, 859,]—criticises it because the kind of dysentery is not stated, and remarks that every dysentery does not, when checked, produce these evil effects; but he himself is not more specific as to the kind of dysentery to the sudden checking of which he ascribes the evil effects enumerated in note †, p. 411, *supra;* indeed he does not limit them to dysentery, but declares that he has known them to result also from hæmorrhoids or other similar discharges (evacuationes hujusmodi) suddenly suppressed by ignorant physicians. PHILUMENUS held similar views—*loc. cit.*, note ¶, p. 735, *supra*. He taught that at the beginning of alvine fluxes we should assist nature in her efforts to get rid of superfluous or noxious matters, and only resort to astringents by the mouth after evacuants have been sufficiently tried and fail to cure, then, indeed, astringents are useful: "In potu vero accepta ventris fluxus post sufficientem inutilium evacuationem sanant"—*loc. cit.* AVICENNA—*loc. cit.*, p. 704, *supra*—wrote: "Et non est conveniens ut in primis incipiat medicinis puris (singularibus) cum qualitatibus suis stypticis et asperis."

and griping pains have subsided under the use of evacuants; and similar cautions are expressed in the writings of Hollerius, Sennertus, Sydenham and Ettmüller.* The experience of subsequent physicians led them very generally to the adoption of these views. It would be easy, but it is hardly necessary, to multiply examples. Let it suffice to refer, in illustration, to the utterances of Hoffmann, Degner, van Swieten, Pringle, Tissot, Zimmermann and Cullen in the last century,† and to Fournier and Vaidy, Broussais, Naumann, Copland, Savignac, Barrallier and Heubner in this.‡

It is true that from the earliest times there have been physicians so rash, or, to use the language of Galen, so ignorant, as to undertake to suppress the discharges at the very beginning of the flux. Degner testified that this was the common practice of the medicasters who abounded at Nimeguen during the epidemic he described; while Tissot affirmed that it was exceedingly common in his day, annually killed a great number of persons, and threw others into incurable disorders.§ It is to be feared that this error is too often

* SAVONAROLA—fol. 178, *op. cit.*, p. 736, *supra:* "Secundo scito quod cum transierint dies decem vel duodecim præsumendum est quod evacuatio facta sit perfecta, et post talem evacuationem poteris uti stipticis." NICOLAUS PISO—p. 276, *op. cit.*, p. 665, *supra:* "Alioqui astringentia febrem augent et inflammationem, vitiosam materiam cohibent, ne foras effluat, eaque cohibita regurgitat sursum, unde gravior febris, convulsiones, et hujusmodi. Adde quod astringentia, ulcera exasperant. Itaque astringentium usus tempestivus est jam vacuata magna ex parte materia, vel ex toto: quumque tempore excernitur cum vitioso humore frugi succus, et inde virium casus metuitur." He suggests that when they are first given, diuretics should be added, that any evil humors remaining may escape by the kidneys and not be thrown back upon the nobler organs. FAB. HILDANUS—Cap. 10, p. 685, *op. cit.*, p. 644, *supra*. HOLLERIUS—Lib. I, Cap. 40, fol. 120, *op. cit.*, p. 680, *supra*. SENNERTUS—T. III, p. 176, *op. cit.*, p. 645, *supra*. SYDENHAM—Sect. IV, Cap. 3, Vol. I, p. 167, *op. cit.*, p. 407, *supra:* "Aphthæ, too, towards the close of the disease, beset the inner parts of the mouth and the fauces, particularly when the body has been long overheated, and when the evacuation of the peccant matter has been checked by astringent remedies, administered before the application of cathartics. These are generally signs of imminent dissolution." ETTMÜLLER—*De morb. human. corp.*, Cap. IX, p. 127, *op. cit.*, p. 647, *supra*—went so far as to declare, "certe nihil pejus est quam uti in dysenteria adstringentibus," but it is clear from his subsequent remarks that he only meant this to apply to their premature employment.

† HOFFMANN—*loc. cit.*, p. 739, *supra*—not only avoided astringents early in this disease, but objected to the use of the more potent articles of this class at any time during its progress. DEGNER—Cap. 5, § 11, p. 268, *op. cit.*, p. 625, *supra*—wrote: "Adstringentibus raro opus erat; excretio enim alvi sua sponte cessabat, postquam venenum aut subactum, aut exactum fuit. In sinu autem concludunt anguem, qui adstringentibus pugnant." Nevertheless, after the use of evacuants, if the flux continued, he sometimes employed catechu and other mild astringents. VAN SWIETEN—§ 722, T. II, p. 392, *op. cit.*, p. 663, *supra*—after praising the use of corroborants and mild astringents in the latter stages of the fluxes, adds: "Verum antequam hæc adhibeantur, certi debemus esse, materiam irritantem expulsam esse, et solam ventriculi et intestinorum flaccidam debilitatem peccare. Si enim adstringentibus alvi fluor sistatur, antequam noxii humores expulsi fuerint, gravissima sæpe mala sequuntur." PRINGLE—Part III, Chap. 6, Sect. 4, p. 275, 1st Ed., cited p. 693, *supra*—wrote: "The hæmorrhage seems to require repeated bleedings and styptics; the flux, strong astringents; and the pains of the bowels, constant opiates: and yet unless these remedies are used with extreme caution, they tend more to augment than cure the disease." This passage is repeated in the subsequent editions. He only used astringents in the third stage of the disease, and then mild ones, such as extract of Campeachy wood, but these he often saw fail, for he writes "when no astringents have availed, I have frequently known the cure obtained by a milk- and farinaceous diet, without them"—p. 283, 7th Ed., cited p. 640, *supra*. TISSOT—*loc. cit.*, p. 740, *supra*—was as severe on the use of astringents as of opiates: "En empêchant l'evacuation de ces matieres, en renfermant le loup dans la bergerie, il arrive, ou 1° que cette matiere irrite les intestins, les enflamme, et de l'inflammation naissent les douleurs horribles, la vraie colique inflammatoire, et ensuite, ou la gangrene et la mort, ou un squirrhe qui dégenere en cancer (j'ai vu ce cas horrible), ou la suppuration, un abcès, un ulcere; ou 2° qu'elle se rejette ailleurs, produit des squirrhes au foye, des asthmes, l'apoplexie, l'épilepsie ou mal caduc, des douleurs de rhumatisme horribles, des maux de yeux, et des maux de peau incurables." ZIMMERMANN—Cap. VII, S. 134, *op. cit.*, p. 648, *supra*—devoted a whole chapter of his work to pointing out the evil effects of astringent and constipating remedies, as well as of aromatics and alcoholic drinks: rheumatic pains and dropsies are the commonest of these. Nowhere is his practical skill better illustrated than by the examples adduced to enforce these precepts; but he shows little acquaintance with the ancients when he accuses them of avoiding evacuants and relying wholly upon restraining remedies: "Die ältern Aerzte kamen darinn in der Heilung der Ruhr so ziemlich überein, dass sie nicht die Materie zum Auswurf zu bringen, sondern sie vielmehr zurückzuhalten, und den Ausfluss durch verdikernde und zusammenziehende Mittel zu hemmen suchten. Auf diese Anzeigen bezog sich ihre Diät, und ihre ganze Heilungsmethode." CULLEN—*First Lines*, § 1086, Vol. II, p. 327, Ed. cited p. 648, *supra*—wrote: "From the account now given of the nature of this disease, [dysentery,] it will be sufficiently obvious that the use of astringents in the beginning of it must be absolutely pernicious." In the remarks added to this paragraph, from his manuscript lectures, by the Editor, he expresses the opinion, however, that astringents may be useful in diarrhœa which merely "consists in an increased evacuation from the exhalents and excretories on the interoal surface of the intestines."

‡ FOURNIER et VAIDY—p. 384, *op. cit.*, p. 362, *supra*—express the opinion that catechu, logwood, tormentil, bistort and other astringents are even more injurious than aromatics in acute dysentery: "La noix de galle, beaucoup plus astringente que toutes ces substances, serait encore plus dangereuse." BROUSSAIS—T. III, p. 226, *op. cit.*, p. 643, *supra*—remarked: "Les astringens augmentent souvent la phlogose en arrêtant la diarrhée. Ils ne manquent point d'opérer ainsi, chaque fois qu'on les donne à dose suffisante pour qu'ils parviennent dans le colon." NAUMANN—Bd. IV, Abth. 2, S. 89, *op. cit.*, p. 645, *supra*—after observing that there is scarcely a single tonic or astringent drug that has not been recommended in dysentery, adds: "Sie können aber, zur unrechten Zeit angewendet, das grösste Unheil anrichten." COPLAND—Vol. I, p. 730, *op. cit.*, p. 682, *supra*—says: "It should be recollected, when prescribing astringents in this disease, that they are injurious when exhibited early in the acute states, and whilst there is much fever, or when morbid matters remain to be evacuated." SAVIGNAC—p. 309, *op. cit.*, p. 620, *supra*—wrote: "S'il est irrationnel de chercher à juguler dès son début la dysentérie par l'opium, il l'est encore plus de l'attaquer par les astringents;" and again, "les astringents sont inopportuns et nuisibles au début de la dysentérie." BARRALLIER—p. 770, *op. cit.*, p. 603, *supra*—observes: "Nous devons dire d'une manière générale que les astringents, nuisibles au début de la dysentérie aiguë, peuvent être utiles seulement dans le cours de la dysentérie chronique;" and HEUBNER—S. 544, *op. cit.*, p. 529, *supra*—expresses the opinion that the experience of several centuries, both in the epidemic dysentery of tropical regions and the epidemics of temperate zones, teaches, "dass die Ruhr nicht unter einer stopfenden Behandlung, sondern unter der Anwendung ausleerender Methoden am günstigsten verläuft und am raschesten heilt."

§ GALEN speaks in the passage referred to in note †, p. 411, *supra*, of the discharges being suppressed in consequence of the ignorance of the physicians, ἰατρῶν ἀμαθείᾳ. DEGNER—Cap. 3, § 87, p. 211 *et seq.*, *op. cit.*, p. 625, *supra*—referring to this matter, wrote: "Vanos sane, fallaces, imo funestos ut plurimum ejusmodi fuisse conatus, facile conjicere potest, qui cognoscit, omnium ejusmodi vitio creatorum Medicastrorum unicum scopum eo collimasse, ut alvi fluxum tantummodo supprimerent et adstringerent, parum soliciti, num materies peccans evacuata, aut satis correcta sit, nec ne." TISSOT—see *loc. cit.*, note ‖, p. 739, *supra*.

imitated in modern times; but those who fall into it do so in despite of the accumulated testimony of the best observers of all ages. Yet the great majority, even of those who have most earnestly cautioned against the rash use of astringent remedies in the early stages of dysentery, have nevertheless employed them with more or less freedom in the advanced stages of the disease and in the chronic fluxes; and the ancient belief that it is possible in this way not merely to restrain excessive discharges, but to favor the healing of intestinal ulcers, when these exist, still survives in modern times.

Concerning the choice to be made among the medicaments under consideration, divers opinions have existed, and from time to time various drugs have held the prominent place in the esteem of practitioners. After the revival of learning in Europe, the Galenists brought into vogue a large number of the remedies employed by their master; and the vegetable astringents, the earths and cretaceous preparations of animal origin figured largely in their treatment of the later stages of dysentery, while, on the other hand, the iatrochemists introduced some of the more potent mineral salts.

Vegetable astringents.—Some of the substances of this kind commended by Galen, especially *galls*, the most important of all, have remained in use to the present day; others sooner or later became obsolete, while new substances came into prominence from time to time. It is not necessary to enter here into tedious details with regard to these, but a few of those most generally used may be briefly alluded to. Among them were *tormentil* and *bistort*, whose virtues in restraining the fluxes are mentioned by some of the herbalists of the sixteenth century, which figured as ingredients in the diascordium of Fracastorius, and occupied a prominent place among the astringents employed in dysentery by Hildanus, Sennertus and many later physicians.* Here, too, belongs *catechu*, known at first as terra japonica and supposed to be an earth, which Garcia de Orta lauded as an astringent in the alvine fluxes as early as 1563; G. W. Wedel commended it in dysentery in 1671, and Degner regarded it as the safest and at the same time the most efficacious astringent that can be employed either in that disease or in diarrhœa.† *Kino*, a very similar though less

* *Tormentil*, (German *Ruhrwurzel*, see C. G. MITSCHERLICH—*Lehrbuch der Arzneimittellehre*, 2te Aufl., Bd. I, Berlin, 1847, S. 239.) the rhizome of *potentilla tormentilla*, the *t. erecta* of LINNÆUS, see PEREIRA—Vol. II, p. 794, *op. cit.*, p. 746, *supra*—still figured in the secondary list of the Materia Medica in the United States Pharmacopœia of 1870, which, however, is not the case with *bistort*, the root of *polygonum bistorta*, see PEREIRA—Vol. cited, p. 437. I will not attempt to fix the date of the introduction of these plants into medicine, or enter into the doubtful question of their identity with plants known to the ancients under other names. It has been conjectured by SPRENGEL—*Hist. Rei Herbariæ*, Paris, 1808, T. I, pp. 43, 93 and 176—that tormentil is the plant known to HIPPOCRATES, THEOPHRASTUS and DIOSCORIDES under the name πεντάφυλλον. Bistort was probably introduced at a much later date. But whatever their early history, we find both highly reputed in the treatment of dysentery in the sixteenth and seventeenth centuries. For the *diascordium* of FRACASTORIUS, referred to in the text, see note §, p. 737, *supra*. JOHN GERARDE—*Herball*, London, 1597, Booke II, Chap. 81, p. 323—says of bistort: "The roote boiled in wine and drunke, stoppeth the laske, and bloodie flixe;" and of tormentil—Chap. 367, p. 840—that the powder of its root "cureth the laske and bloudie flixe, yea although the patient haue adioined vnto his scouring a greeuous feuer." For the use of these and other astringents by HILDANUS and SENNERTUS, see the places in their writings referred to in note *, p. 764, *supra*.

† *Catechu* is an extract prepared from the acacia catechu and other trees. D. BARBOSA—*A Description of the Coasts of East Africa and Malabar in the beginning of the sixteenth century, by Duarte Barbosa, a Portuguese;* translated from an early Spanish manuscript in the Barcelona library, with notes and a preface, by the Hon. HENRY E. J. STANLEY, London, printed for the Hakluyt Society, 1866, p. 191—mentions "a drug which we do not possess," called *cachó* among the exports from Cambay to Malacca, but says nothing of its properties. FLÜCKIGER and HANBURY—*Pharmacographia*, p. 213, Ed. cited p. 703, *supra*—quote this statement with the remark: "This is the name for Catechu in some of the languages of Southern India." The medicinal virtues of this drug were first described by GARCIA DE ORTA—*Colloquios dos Simples e Drogas*, &c., Goa, 1563; I have not seen the original, which is very rare, but cite from a modern reprint, Lisbon, 1872, p. 125 *et seq.*—who described it under the name of *cate*, and claimed that it was useful in checking fluxions of the eyes, strengthening the gums and teeth, "and that it was useful to the throat, in cases of lumbricoids, and in looseness of the bowels," (e aproveita pera a garganta e pera as lombrigas e pera as camaras.) C. CLUSIUS (DE L'ÉCLUSE) published an epitome of GARCIA'S work—*Aromatum, et Simplicium aliquot Medicamentorum apud Indos nascentium Historia*, Antwerp. 1574, Lib. I, Cap. 10, p. 46—from which I extract the following description of its virtues: "Optimum est medicamentum non modo ad confirmandas gingivas, et desiccandum et constringendum; verum etiam ad alvi profluvia curanda, oculorumque dolores tollendos, in quibus plerunque optimo cum successu usus sum." I note that STILLÉ—Vol. I, p. 231, *op. cit.*, p. 711, *supra*—writes: "Its medicinal qualities were first described, in 1601, by Garzia del Huerto," &c., but as he cites no authority, I know not how he fell into this error of date. GARCIA regarded catechu as identical with the *lycium* of DIOSCORIDES—Lib. I, Cap. 133, fol. 52, Ed. cited p. 623, *supra*—but this view has been disputed by J. F. ROYLE—*On the lycium of Dioscorides*, Transactions of the Linnean Society of London, Vol. XVII, 1837, p. 82—and must be regarded as a mere conjecture. GARCIA knew very well that catechu was the juice of a tree, which he correctly described as well as the manner of preparing it, but notwithstanding the publicity given to his writings by CLUSIUS, whose Epitome ran through five editions, (the 5th printed at Leyden in 1605,) when the drug first found its way to Europe it was supposed to be an earth, and was called terra Japonica. J. SCHRŒDER—*Pharmacopœia Medico-Chymica*, 4th Ed., Lyons, 1654, which I have not seen, and cite from the *Pharmacographia*, p. 214—described it under this title as "genus

energetic astringent, was first brought into general notice in connection with the treatment of the fluxes in 1757 by Fothergill, to whom Oldfield had communicated his observations of its usefulness in chronic diarrhœas.* *Logwood* came into use a little earlier; its extract was already prescribed in the advanced stages of dysentery by Pringle in 1751.† The astringent virtues of *rhatany* were made known in 1796 by Ruiz, who commended it in the treatment of fluxes of blood of all kinds, and in 1806 by Reece, who lauded it in several disorders, among others in chronic dysentery and lientery.‡

Various other vegetable astringents have been employed, but it is unnecessary to enumerate them here.§ All are believed to owe their virtues to the presence of principles belonging to the tannin group. Between these, slight chemical differences have been generally admitted to exist,‖ but there is no satisfactory evidence of any material differences in their chemical nature, and it has even been claimed that all they are capable of doing in the alvine fluxes may be effected by the officinal tannic acid.¶ Accordingly *tannin*, the

terræ exoticæ." G. W. WEDEL—*Usus novus catechu, seu terræ Japonicæ*, Misc. Cur. German., Dec. I, an. 2, 1671, Obs. 128, p. 209—mentions that when he wrote it was regarded as an earth by some, by others as an expressed juice, while others believed it to be a compound. He added a short paper—*Tinctura catechu styptica*, Obs. 130, same Vol., p. 211—in which he praises the virtues of the tincture in the fluxes, including dysentery, "in ipsa dysenteria." L. SCHROECK—*De catechu*, same Jour., Dec. I, an. 8, 1677, Obs. 54, p. 88—argued in favor of its vegetable nature, which was established by the subsequent observations of J. O. HELBIG—*De rebus variis Indicis*, same Jour., Dec. I, an. 9 et 10, 1678-9, Obs. 194, § 26, *Cautchu*, p. 463; A. CLEYER—*De catechu*, same Jour., Dec. II, an. 4, 1685, Obs. 3, p. 6; and others. See, besides the above citations, PEREIRA—Vol. II, p. 832, *op. cit.*, p. 746, *supra*. DEGNER—Cap. 5, § 12, p. 269, *op. cit.*, p. 625, *supra*—declared that when, after the removal of the cause of the flux, (by evacuants,) it still continued, simaruba or cascarilla bark and the succus catechu can supply the place of all other tonics and astringents. In a foot note he chiefly praises the last two, remarking, "in diarrhœis, dysenteriis, similibusque alvinis fluxibus, efficacissima sane et tutissima sunt remedia."

* *Kino* is the inspissated juice of the *pterocarpus marsupium* and other plants: see PEREIRA—T. II, p. 824, *op. cit.*, last note; STILLÉ—T. I, p. 237, *op. cit.*, last note; and the *Pharmacographia*, p. 170. Attention was first attracted to its medicinal virtues by FOTHERGILL—*A letter from Dr. John Fothergill, to the Medical Society, concerning an astringent gum brought from Africa*, Med. Obs. and Inquiries, Vol. I, London, 1757, p. 358—who suggested its use in the fluxes in consequence of the good effects obtained with it by OLDFIELD in a case of "obstinate chronical diarrhœa." See also C. A. SCHENCK—*Diss. inaug. chemico-med., sistens gummi-kino usum ejusque virtutes*, Marburg, 1784—who brings forward the testimony of SCHAEFER and EBELIN, as well as FOTHERGILL, as to its virtues in inveterate diarrhœas—p. 30.

† *Logwood*, the heart wood of the *hæmatoxylon Campechianum*, was first introduced into Europe as a dyestuff, and was not employed in medicine until shortly before 1746, when it was introduced into the London Pharmacopœia under the name of lignum tinctile Campechense: see the *Pharmacographia*, p. 186, and PEREIRA—Vol. II, p. 837, *op. cit.*, last note. An extract of this wood was already in use in 1751, and its use in dysentery was recommended by PRINGLE in the first edition of his work—p. 285, Ed. cited p. 693, *supra*. His prescription was: "℞. Extract. Lign. Campech. 5iij. Solv. in Aq. Cinnamom. spir. 3j. add. Aq. fontan. 3vij. Tinct. Japonic. 5ij. M." The dose was "two spoonfuls once in four or five hours." The same formula figures in his account of the treatment of the third stage of the disease in the 7th edition, p. 281.

‡ *Rhatany* is the root of the *krameria triandra*: see PEREIRA—T. II, p. 995, *op. cit., supra*; STILLÉ—T. I, p. 238, *op. cit., supra*; and the *Pharmacographia*, p. 74. Its virtues as an astringent were first pointed out by HIPOLITO RUIZ in a dissertation published in the first volume of the *Memoirs of the Royal Academy of Medicine of Madrid*, 1797, which I have not seen, but cite the French translation of BOURDOIS—*Diss. sur la racine de la ratanhia. Traduite de l'espagnol, en l'an* 1806, *par ordre du Ministre des Relations Extérieures*. He recommended it in excessive menstruation and in fluxes of blood of all kinds, as well as to arrest hæmorrhage from recent wounds by its local action and as a mouthwash—p. 16. RICHARD REECE published an article on the medicinal virtues of this root and its extract in the London Medical and Chirurgical Review, Vol. XIII, 1806—I cite from the *Pharmacographia*, the volume being missing from the file of this journal in the Library of the Surgeon General's Office—and in a separate pamphlet—*Pract. obs. on the radix rhataniæ, or, rhatany root, a production of Peru*, London, 1808. It seems that shortly before, the cargo of a Spanish prize was sold in the London drug market, and it thus fell into his hands. He recognized its astringent virtues, which he employed in various diseases, and gives a formula for its use in chronic dysentery, lientery, &c. See also the dissertation of E. L. A. V. ECKARD—*De radice rataniæ*, Berlin, 1822—who praises it highly in diarrhœa and rheumatic dysentery—p. 24.

§ The list would embrace not only all the officinal vegetable astringents but many others. I have made no attempt to collect the scattered commendations of these substances. The following papers, which I find mentioned in my notes, are only referred to here as illustrations of their character: JAMES WOODHOUSE—*An inaug. diss. on the chemical and medical properties of the persimmon tree*, Philadelphia, 1792; D. M. P. REISS—*Note sur l'emploi de l'extrait d' ai relle myrtille dans la diarrhée*, [vaccinium myrtillus, Linn.,] Jour. de Méd., T. I, 1843, p. 115; J. C. C. BLACKBURN—*The strawberry leaf, a valuable auxiliary in the treatment of chronic dysentery*, Southern Med. and Surg. Jour., Vol. III, 1847, p. 657; C. HANDFIELD JONES—*Note on the use of Ashantee bark in chronic dysentery*, The Brit. Med. Jour., Vol. I for 1871, p. 588; LEVRAT-PERROTON—*Obs. sur l'emploi de la renouée* [polygonum aviculare] *dans la diarrhée*, Revue Méd. Française et Étrangère, T. III, 1845, p. 421; J. C. WHITEHILL—*On the treatment of chronic diarrhœa and dysentery, with a decoction of the inner bark of the pine tree*, Med. Archives, St. Louis, Vol. VI, 1871, p. 327; A. D. BINKERD—*Therapeutic value of the fresh pecan* [nuts] *in subacute diarrhœa*, The Med. and Surg. Reporter, Vol. XXXII, 1875, p. 58; S. C. PARSONS—*Cota bark in the diarrhœa of children*, The Med. Record, (N. Y.,) Vol. XIV, 1878, p. 288.

‖ According to A. and T. HUSEMANN—*Die Pflanzenstoffe*, Berlin, 1871, S. 996—the tannic acid of galls was discovered by DEYEUX in 1793 and SEGUIN in 1795. With regard to the chemistry of the bodies of this group, consult L. GMELIN—*Hand-Book of Chemistry*. Translated by Henry Watts, London, printed for the Cavendish Society, Vol. XV, 1862, p. 449 *et seq.* The HUSEMANNS suggest—*op. cit.*, S. 526—that further investigation may perhaps show the actual identity of many of these bodies: and if the new views with regard to the nature of tannic acid (see note ‖, p. 768, *infra*) are correct, this is probable enough. Both their work and that of GMELIN contain good references to the bibliography of the subject up to date of publication.

¶ As to the physiological and therapeutical effects of tannic acid, see J. CLARUS—*Handb. der Spec. Arzneimittellehre*, 3te Aufl., Leipsic, 1860, S. 454; STILLÉ—Vol. I, p. 220 *et seq., op. cit., supra*; NOTHNAGEL—S. 315 *et seq., op. cit.*, p. 746, *supra*; H. C. WOOD—p. 26 *et seq., op. cit.*, p. 675, *supra*; and BUCHHEIM—S. 418 *et seq., op. cit.*, p. 746, *supra*. CLARUS classes the various vegetable astringents under the head of "medicamenta tannica," NOTHNAGEL, as "tanninhaltige Mittel," BUCHHEIM, as "Gruppe der Gerbsäuren." NOTHNAGEL remarks: "Die Gerbstoffe in den verschiedenen Pflanzen differiren etwas in ihrem chemischen Verhalten, doch haben wir bis jetzt keine Anhaltepuncte dafür, dass dies auch einen merklichen Unterschied in physiologischer oder therapeutischer Beziehung bedingte." With this I heartily agree; I have been unable to find satisfactory evidence of any difference in therapeutical action even between the tannins which strike a blue-black (gallo-tannic acid) and those which strike a green-black (kino-tannic acid) color with the persalts of iron.

so-called tannic acid, generally believed to represent substantially the active principle of the astringent simples, has to a considerable extent replaced them of late years in the treatment of the fluxes. Not only is it conveniently administered in pill form, and readily given in definite doses, but it was hoped that it would afford the means of restraining excessive discharges from the bowels more energetically than can be done by the astringent simples, unless they are given in inconvenient bulk. Tannin has hence been recommended in the advanced stages of dysentery, and in chronic fluxes, by Bertini, Waidele, Clarus and others.* During our civil war it was frequently employed in these conditions, generally in connection with opium, and Stillé has expressed the opinion that no remedy proved comparable to this combination in efficacy.†

But the general tenor of recent clinical experience is by no means in accord with this favorable view, and probably the majority of practitioners will agree with Niemeyer, that if acetate of lead or some other favorite mineral astringent fails, no great good is to be expected from tannin or any of the vegetable substances that contain it.‡ And in fact the little that is known concerning the physiological action of tannin seems to indicate that its range of usefulness in the fluxes must be comparatively limited. Although its astringent influence upon the mouth and fauces and upon external wounds or ulcers is decided, its operation in the stomach is of a much less powerful character, for a part of it is speedily precipitated with the mucus and albuminous compounds of the gastric contents in the form of insoluble and probably quite inert tannates, while the rest is rapidly converted into gallic acid.§ Indeed, it may well be questioned whether, when tannin is administered by the mouth, any of it reaches the intestinal canal unless it be given in considerable doses, or perhaps in the form of pills, some undissolved portion of which may be hoped to pass the pylorus unchanged.‖

These considerations warrant the expectation that the astringent effect of tannin upon the bowels would prove much less energetic than might be anticipated from its behavior when used as an external application; and this expectation is corroborated by the phenomena observed after notable quantities of the drug are swallowed by healthy individuals. Mitscherlich reported that the temporary constipation, frequently produced by the administration of ten to twenty grains three times daily, generally ceased spontaneously after two

* B. BERTINI—*Quelques observations pratiques sur l'utilité du tannin dans les diarrhées invétérées et rebelles aux moyens ordinaires*, (translated from the Giornale delle scienze mediche, pubblicato della Accademia reale di Torino, nº de Mars 1846,) Gaz. Médicale de Montpellier, April, 1846, p. 12—gave 10 to 20 grains of tannic acid twice daily in obstinate diarrhœas. WAIDELE—*Ueber die Behandlung der Ruhr*, Memorabilien aus der Praxis, Jahrg. I, 1856, No. 23—used it both internally and as an enema in acute dysentery when the alvine discharges continued after the tormina ceased. CLARUS—S. 463, *op. cit.*, note ¶, last page—states that he has frequently employed it, and found it most useful in the chronic intestinal catarrhs of children and in chronic dysentery.

† See Section II of this chapter, where tannic acid is commended as a remedy in chronic diarrhœa by SCHÖSSLER—p. 44, *supra;* B. WOODWARD—p. 51, (who, however, preferred gallic acid when he could get it;) BLAKESLEE—p. 76; BRETZ and SCHEETZ—p. 80; GRIMES—p. 86; WALTON—p. 88; and COOPER—p. 93. On the other hand, BROWN—p. 81—declared that he had made a thorough trial of it without good results. Other vegetable astringents, such as kino, catechu, oak-bark, or, indefinitely, "vegetable astringents," are commended by STORROW—p. 43; WOOD—p. 74; HOYT and SCHEETZ—p. 80. On the other hand, PENROSE—p. 45—reported that they "palliate rather than cure;" and BIGELOW—p. 83—that he had tried them without avail. STILLÉ—Vol. I, p. 223, *op. cit.*, p. 711, *supra*—thinks tannic acid more useful in the chronic fluxes "than any other medicine of its class, even more so, perhaps, than the acetate of lead." He adds: "During the late civil war we found, during an extensive and prolonged hospital practice, no remedy for chronic diarrhœa and dysentery at all comparable to tannic acid associated with opium and a strictly regulated milk diet." But how much of the apparent success, which this physician observed at Satterlee hospital, was due to the drug? how much to the milk diet and change of climate?

‡ NIEMEYER—Bd. II, S. 756, *op. cit.*, p. 645, *supra:* "Lässt auch diese Behandlung im Stich, so ist von der innerlichen Darreichung des Argentum nitricum und den vegetabilischen Adstringentien, namentlich dem Tannin, noch weniger zu erwarten."

§ See, on this subject, the testimony of CLARUS, STILLÉ, NOTHNAGEL, H. C. WOOD and BUCHHEIM, cited note ¶, last page. The insoluble tannates thus formed are discharged by stool, while the gallic acid is absorbed and eliminated by the urine.

‖ CLARUS expresses the opinion that if tannic acid is given in sufficient doses, it may reach the intestine unchanged and exercise its characteristic effects by diminishing secretion, precipitating mucus and albuminates, and acting as an astringent. In consequence of this latter effect, he thinks it may even act as a vermifuge, the entozoa and their eggs being mechanically entangled in the precipitate, and so readily driven along by the peristaltic movements. We are, however, entirely without experimental evidence as to the quantity of tannic acid that must be given before any of it can reach the intestine unchanged. H. C. WOOD—*loc. cit.*—remarks: "When the bowel is to be influenced, as in diarrhœa, the drug should be administered in pill (three to five grains), so that, if possible, it may pass the pylorus undissolved."

or three days without the necessity of employing laxatives.* Still more noteworthy were the observations Tully made on himself, and which were repeated by several of his students; ten grains taken four times daily for about a week exercised no more constipating effect than if they had eaten "so much maize meal."† Nor is it advisable to endeavor to obtain greater effects from the drug by more considerable doses. Even in healthy individuals these produce loss of appetite, gastric uneasiness, vomiting, sometimes even diarrhœa,‡ and in patients whose digestion is already disordered they are not to be thought of.

Accordingly it is not surprising that some physicians should agree with Savignac in claiming that catechu, rhatany and other simples possess a special efficacy of their own, and produce better results in the fluxes than can be obtained from pure tannin,§ although it would seem that this view represents the survival of ancient prejudice quite as much as logical deduction from observed facts. Indeed, in view of the great probability that any astringent operation exerted in the intestine after the ingestion of tannin is due to the gallic acid into which it is transformed, it would seem more rational to resort to this acid as a substitute; and if it be true, as recent chemical researches seem to show, that tannin is merely an anhydride of gallic acid,‖ we may thus hope to imitate better the effects of the astringent simples, and at the same time retain the advantages of using a substance which may be given in definite dose, free from the admixture of foreign, inert or objectionable matters.

This choice has already been made, though on other grounds, by Bayes, Young and other physicians,¶ who have commended *gallic acid* in diarrhœa and dysentery. It is well worthy of further trial. Although less energetic than tannin when externally applied, it is probable that a greater astringent effect can be produced in the intestine by its use; moreover, it is readily absorbed into the circulation,** and appears to owe a part of its

* MITSCHERLICH—Bd. I, S, 249, *op. cit.*, p. 765, *supra*—on the strength of these observations, criticises CAVARRA—*Du tannin*, &c., Bull. Gén. de Thér., T. XII, 1837, p. 165—who states that having taken himself 2½ grains three times daily for three days, an obstinate constipation resulted which lasted eight days, and only yielded to two drops of croton oil. "Diese Beobachtung," writes MITSCHERLICH, "wird gewiss selten bestätigt."

† WILLIAM TULLY—*Materia Medica*, Vol. I, Part 2, Springfield, (Mass.,) 1858, p. 1112. He adds: "Subsequently a similar trial of this agent was made by several of my professional pupils, and with no more effect as respects the intestinal discharges, than upon myself;" and declares further: "I was never so fortunate as to arrest a case of diarrhœa with this article, since I first had knowledge of it, though I have administered it in small doses and large, at short intervals and long, and have employed it both perseveringly and transiently, and in a considerable number of cases."

‡ MITSCHERLICH—*loc. cit.*, *supra*—writes: "Zu grosse Gaben dagegen machen Magendrücken, Übelkeit, Erbrechen, seltener Diarrhöe, die Zunge wird belegt und der Appetit geht verloren." TULLY—*loc. cit.*—says of the doses taken by himself and his students: "The article nauseated a little however, and impaired the appetite considerably." NOTHNAGEL—*loc. cit.*, note ¶, p. 766, *supra*—testifies: "Auf sehr grosse Gaben entsteht Würgen. Erbrechen, Durchfall und weiterhin der andere Symptomencomplex einer acuten Gastro-Enteritis;" and BUCHHEIM—S. 420, *op. cit.*, p. 746, *supra:* "Nach grösseren Dosen (1–2 Grm.) tritt ein unangenehmes Gefühl in der Magengegend, Aufstossen und Uebelkeit und auch wohl Erbrechen ein."

§ SAVIGNAC—p. 400, *op. cit.*, p. 620, *supra:* "Mais, soit que d'autres principes exercent aussi une certaine action, soit que les tannins modifiés qui se trouvent dans le cachou, le ratanhia, le kino, etc., aient une efficacité spéciale, il est positif que ces substances et leurs analogues produisent de meilleurs effets que le tannin pur." Further on he expresses a decided preference for catechu and rhatany. I may add that SAVIGNAC altogether rejects mineral astringents in the treatment of dysentery, with the single exception of perchloride of iron.

‖ A. and T. HUSEMANN—S. 1001, *op. cit.*, p. 766, *supra*—have sketched the earlier studies in this direction: LIEBIG had shown that by boiling with dilute sulphuric acid, tannin is converted into gallic acid. At the same time, according to STRECKER, glucose is formed; and it was supposed that the tannin broke up into gallic acid and glucose. But the observations of STENHOUSE, and of ROCHLEDER and KAWALIER, demonstrated that the quantity of glucose thus obtained is less and less in proportion as the tannin is purer, and that when the sulphuric acid is sufficiently dilute, almost the whole mass of tannin is transformed into gallic acid. H. HLASIWETZ—*Ueber die Beziehungen der Gerbsäuren, Glucoside, Phlobaphene und Harze*, Ann. der Chemie und Pharm., Bd. CXLIII, 1867, S. 295—from these and his own investigations, concluded that tannin is really composed of two equivalents of gallic acid less one of water, so that it may be regarded as a digallic acid. The experiments of SACE—*Recherches sur la formation de l'acide gallique*, Comptes rendus, T. LXXII, 1871, p. 766—point strongly in the same direction. He found that a sample of powdered galls yielded to ether 43 per cent. of pure dry tannic acid, while some of the same lot yielded, after three months' fermentation with water, 50 per cent. of pure dry gallic acid. He concluded, therefore, that the change was one of simple hydration, and that "tannic acid is probably only the anhydride of gallic acid." A similar conclusion has been reached by H. SCHIFF, whose work appeared so important to A. WURTZ that he translated it into French—*Sur la nature et la constitution de l'acide tannique*, Ann. de Chimie et de Physique, T. XXV, 1872, p. 182. SCHIFF concludes: "Tannic acid is an alcoholic anhydride of gallic acid, that is to say very probably of digallic acid."

¶ W. BAYES—*On gallic acid*, [read before the Medico-Chirurgical Society of Brighton and Sussex, Nov. 3, 1853,] Association Med Jour., Vol. for 1854, p. 506—commended it in both diarrhœa and dysentery, and appears to have preferred it chiefly on account of "the ease and rapidity with which it enters the blood." G. H. YOUNG—*On asthenic dysentery*, Dublin Quart. Jour. of Med. Sci., Vol. XX, 1855, p. 70—advised gallic acid in asthenic dysentery: "Gallic acid to allay the hemorrhage, quinia to support the sinking powers of life, and opium as the *sine quâ non* in any treatment of dysentery"—p. 73. T. H. TANNER—p. 664, *op. cit.*, p. 751, *supra*—mentions it among other astringents in connection with the treatment of advanced dysentery: "Bismuth, gallic acid, kino, logwood, iron alum, or sulphate of copper."

** Even when tannic acid is given, it is only the gallic acid into which it is transformed that is absorbed, and after absorption excreted by the kidneys: see the authorities cited in note ¶, p. 766, *supra*.

influence to that circumstance. Far less likely to disturb the stomach than tannin, it may be given in the dose of ten grains to half a drachm, or even more, three times daily, without any injurious effect.* But no more from it than from tannin is any very positive restraining influence upon the bowels to be expected;† and indeed it may well be doubted whether it is worth while to resort to it or to any of the vegetable astringents, except in mild fluxes dependent upon mere irritation or subacute inflammation of the intestinal mucous membrane, and even in these it will often be found the desired effect can be more satisfactorily attained by other means. The great reputation these medicines enjoyed in former times was probably due chiefly to the circumstance that they were almost always given in combination with opium, and the injurious effects they were so often accused of producing, when used prematurely in dysentery, were doubtless caused to a great extent by the constipating influence of that powerful drug.

Besides its role as a mild astringent in the conditions just indicated, gallic acid may perhaps prove useful in controlling hæmorrhages from the bowels arising during the progress of any of the alvine fluxes. Morehead has related one case of hæmorrhagic dysentery, that occurred in the practice of Leith, in which this plan of treatment was employed with success, and Alde has reported another, but Gordon has testified to its trial without success in similar cases:‡ and it must be admitted that the determination of its precise range of usefulness in such hæmorrhages requires further study.

Mineral astringents.—Of the substances belonging to this group *alum* was commended, in the writings of Ætius, as a readily obtainable remedy useful in chronic dysenteries and in those accompanied with bloody discharges; he directed it to be rubbed up with an egg and given with draughts of warm water.§ This combination was still occasionally used in dysentery as late as the latter part of the sixteenth century, when it was advised in the treatise of Hollerius.‖ We have the testimony of Schrœder that during the seventeenth

* According to MITSCHERLICH—S. 242, *op. cit.*, p. 765, *supra*—large doses of tannic acid (half an ounce) administered to rabbits produce a local caustic effect on the gastric and even the intestinal mucous membrane, and death soon follows. SCHROFF—*Lehrb. der Pharm.*, 1te Aufl., which I have not seen, and quote from CLARUS—S. 480, *op. cit.*, p. 766, *supra*—obtained similar results, but according to him gallic acid produces much slighter effects upon the gastro-intestinal mucous membrane of these animals. BAYES—*loc. cit.*, note ¶, last page—states that "when an overdose of gallic acid has been taken, [by a human subject,] the pulse becomes small and wiry, the face grows pallid, a whizzing sound is heard in the ears, the head feels dizzy, and faintness supervenes." He attributed these symptoms to an astringent effect exercised upon the cerebral vessels, and adds: "But I conceive it would not be possible to poison a patient by the largest dose of the remedy when introduced by the mouth, because the capillary and distal vessels would become too contracted to receive any further supply, long ere a sufficient quantity could be carried into the blood to produce dangerous effects upon the central circulation." One of the advantages he claimed for gallic acid was "the perfect safety with which the largest dose may be administered." However lightly we may esteem the speculations of this writer, his practical suggestions are well worthy serious consideration.

† SIMPSON, indeed, is reported to have said in the Medico-Chirurgical Society of Edinburgh, April 19, 1843—The Lond. and Edinb. Monthly Jour. of Med. Sci., Vol. III, 1843, p. 661—while recommending gallic acid in menorrhagia: "It had this advantage over most other anti-hemorrhagic medicines, that it had no constipating effect upon the bowels."

‡ MOREHEAD—p. 308, *op. cit.*, p. 657, *supra*—reports but a single case of this kind treated with gallic acid and tincture of catechu—the latter an unnecessary addition: "Eight grains of the former and two drachms of the latter were given every hour and a half alternately, and port wine was at the same time freely used. The case was one of hæmorrhagic dysentery, with adynamic phenomena, in a European officer, and recovery was complete." ALDE—*Traitement de la dysenterie par l'acide gallique*, Annuaire de Thérapeutique, 22e année, Paris, 1862, p. 198—relates another successful case: A young Damascene suffering from dysentery in Alexandria, Egypt, was treated by him with ipecacuanha and opium; and troublesome hæmorrhage, which occurred several times during the progress of the case, was readily controlled with gallic acid. A bilious diarrhœa remaining, after the violence of the attack had subsided, was checked by a combination of tannin and bismuth. C. A. GORDON—*Experiences of a regimental surgeon in India*, The Med. Press and Circular, Vol. VII, 1869, p. 179—says of LEITH'S method as reported by MOREHEAD: "This plan was, with many others, tried in the 10th Regiment, but, unhappily, without the success attributed to it by the author named."

§ ÆTIUS—Tetrab. III, Serm. 1, Cap. 48, p. 612, Ed. cited p. 656, *supra:* "Aliud parabile. Alumen liquidum tritum cum ovo absorbendum præbe, et rursus aqua calida dilutum bibendum exhibe, et admiraberis. Sedât diuturnas dysenterias, et in quibus cruenta excernuntur." The styptic virtues of alum were early recognized by the Greeks, as is indicated by the name they gave it, stypteria, [στυπτηρία,] which, as we are told by GALEN, implies astringency: "Hujus medicamenti nomen ab astrictione deductum est, nam adest illi vehementissima"—*De simp. med. temp. ac fac.*, Lib. IX, Cap. 3, § 30, [Ed. Kühn, XII, 236.] He enumerated it among the substances which favor the cicatrization of ulcers without acting as caustics—same treatise, Lib. V, Cap. 15, [Ed. Kühn, XI, 756,]—and frequently used it as an ingredient of clysters, but does not appear to have administered it internally in the fluxes. I presume, with ADAMS, in his commentary on the account of alum given by PAULUS ÆGINETA—Lib. VII, Cap. 3, Ed. cited p. 624. *supra*, Vol. III, p. 360—that the Greeks understood by alum chiefly the same substance we now call by that name, though perhaps they may have included other substances, such as sulphate of iron, and alum contaminated with various impurities.

‖ HOLLERIUS—*De morb. intern.*, Lib. I, Cap. 40, fol. 122, *op. cit.*, p. 680, *supra*. His formula was, "alumen tritum ʒj pondere ex ovo." This recommendation and the passage from ÆTIUS are cited by SENNERTUS—T. III, p. 177, *op. cit.*, p. 645, *supra*—who, however, does not appear to have employed the remedy.

century alum was employed by some physicians as an astringent in dysentery;* but this practice could not have attained any great notoriety, for I have found no allusion to it in any of the treatises on dysentery of that age I have consulted.

During the latter part of the last century, and the beginning of this, alum came into more general use for this purpose. About the year 1784 Adair employed it in an epidemic of dysentery, and regarded it as the safest astringent he had tried.† Birnstiel, in 1786, lauded a combination of alum and camphor as a prophylactic against dysentery;‡ Michaelis gave it in powder or dissolved in whey with alleged advantage in the Harburg dysentery of 1797;§ and Leib attributed to it the cure of a case of chronic dysentery which he treated in 1791.‖ Moseley employed alum in combination with sulphate of zinc, not only in chronic diarrhœa and dysentery, but also in the early stages of slight dysenteries, and even of more serious cases, when for any reason his favorite sudorific process could not be put into practice.¶ Other combinations of this salt were employed in dysentery by Hargens and Loos.** Moseley's mixture appears to have found most favor, and Jackson, in 1817, still reckoned it among the useful remedies.††

The purgative effect of large doses of alum had been recognized by Cullen,‡‡ as well as by Adair, but neither regarded this a contraindication to their use. On the other hand, Quarin regarded it as unsuitable in dysentery for this among other reasons; while Fournier and Vaidy pointed out as a further objection that it augmented the abdominal pains.§§ Bampfield especially criticised the combination used by Moseley, declaring that it is difficult to adapt the proportion of alum to the astringent effect desired; that when it constipates the tormina are increased; and that it sometimes induces an actual relapse.‖‖

---

* J. SCHRŒDER—*Pharmacopœia Med.-Chym.*, Ulm, 1641; I cite from the extracts on alum in the work of MANGETUS—T. II, p. 755, *op. cit.*, p. 736, *supra*, and the 4th German edition of SCHRŒDER'S book, Theil II, Nuremberg, 1747, S. 967: "A few give alum also in bloody dysentery, (in der rothen Ruhr:)" he states also that certain empirics gave it internally in fevers.

† JAMES ADAIR in a letter to A. DUNCAN—Med. Comm. for the years 1783-84, Vol. IX, London, 1785, p. 209. He gave it in the dose of 10 to 30 grains, and says: "In a late epidemic dysentery, I used it with advantage; the vitriolic acid combined with earth of alum renders it sedative and antiseptic; and as it is at the same time eccoprotic, in a large dose, it is the safest astringent I have hitherto tried. Dr. Percival's remarks on this drug, led me to try it early and boldly." On account of "its ungrateful stimulus in the stomach," he mitigated it "by spermaceti, gum arabic, or opium." Now I note that PERCIVAL—*Essays;* I cite the 4th Ed., Vol. I, London, 1788, p. 401—who, following the example of J. GRASHUIS—*De colica pictonum*, Amsterdam, 1755—gave alum in lead colic, commends it only "in various painful affections of the bowels, of the chronic kind, and not attended with inflammatory symptoms"—p. 406.

‡ F. H. BIRNSTIEL—*De dysenteria liber*, Mannheim, 1786, p. 311 *et seq.*

§ MICHAELIS—*Epidemische Constitution zu Harburg*, Hufeland's Jour., Bd. VI, St. 1, Neue Aufl., 1811, S. 180.

‖ M. LEIB—*Case of dysenteria chronica cured by alum*, Trans. of the College of Physicians of Philadelphia, Vol. I, Part 1, 1793, p. 225. He gave it with opium and Peruvian bark, but remarks: "Lest it might be supposed that the cure was owing to the other medicines which were exhibited with the alum, it may be proper to remark, that they were administered for a long time without the alum, and without effect." In this, as in so many other cases, the last remedy tried was duly credited with the cure.

¶ MOSELEY—p. 384, 2d Ed., 1789, and p. 386, 3d Ed., 1792, *op. cit.*, p. 648, *supra*—dissolved three drachms of sulphate of zinc with one of rock alum and three grains of cochineal in a pound of hot water, and strained or filtered. Dose from a teaspoonful to a tablespoonful, to be taken in the morning fasting, and in some cases to be repeated every six hours. "This," he remarks, "I have found far more efficacious in the dysentery, than emetic tartar, ipecacuanha, rhubarb, or salts, as evacuants, in whatever manner combined, or administered." He varied the proportions according to circumstances, diminishing or omitting the alum "when evacuations are required," and increasing it "when great astringency is required." The emetic effect often produced did not daunt him, and when it griped, as it sometimes did, he tried to check that effect with laudanum.

** HARGENS—*Ueber die epidem. Constitution zu Kiel, etc., im Jahr* 1798, Hufeland's Jour., Bd. VII, St. 3, 1799, S. 137—advised half a grain of opium with 10 to 15 grains of alum, to be taken as many times daily as the circumstances of the case seemed to indicate. LOOS—*Kurze Bemerk. über einige verkannte Arzneimittel*, Horn's Archiv, Bd. IX, 1810, S. 193—commended a combination of alum with opium, to be given in a decoction of tormentil root and oak-bark.

†† R. JACKSON—*Febrile Diseases*, London, 1817, p. 442: "Angustura bark, arnica, gentian, camomile, etc., camphorated mixture with white vitriol and alum and acetated water of ammonia given at frequent intervals, may be reckoned among useful remedies: they contribute materially to accelerate recovery and to secure against the chances of relapse." In the second edition of his work, London, 1820, Vol. II, p. 60 *et seq.*, this passage is omitted, but injections of white vitriol and alum are commended on p. 64.

‡‡ CULLEN—Vol. II, (1789,) p. 17, *op. cit.*, p. 740, *supra*—wrote: "I am surprised to find that it seems not to have been employed with other astringents in diarrhœa. Some materia medica writers indeed mention its being suited to cure this disease; but I have not met with any practical writer who prescribes it in such cases." On the next page he remarks: "It is ready to irritate the stomach: and in several instances I have found it rejected by vomiting; and what is more extraordinary, I have known large doses of it operate as a purgative." He does not allude to its use in dysentery, in which, as he thought all astringents hurtful, he would not have thought of resorting to it.

§§ J. L. B. DE QUARIN—*Animadversiones Practicæ in Diversos Morbos*, (1786,) Ed. aucta, Vienna, 1814, T. II, p. 220: "Alumen, quod putredini adversatur, et colliquationem humorum impedit in dysenteria putrida non convenit, cum alvi fluxum moveat." FOURNIER et VAIDY—p. 384, *op. cit.*, p. 362, *supra*.

‖‖ BAMPFIELD—p. 197, *op. cit.*, p. 682, *supra*.

These representations served to limit the use of alum as an internal remedy in the fluxes, and it has rarely been employed in this way in recent times.* Increased knowledge of its mode of operation has only served to increase the objections to its use. Swallowed in small doses it forms precipitates with the gastro-intestinal secretions and contents, and the mucous membrane is thus protected from its injurious action; but in larger doses the excess provokes serious gastro-intestinal irritation, and colicky pains accompany the vomiting and purging that result; long continued, it is capable of producing a grave gastro-intestinal catarrh.† It seems, therefore, ill-adapted for internal use in the fluxes, although, as the irritant is expelled with the evacuations, it is usually administered with impunity when the alimentary canal is free from disease.

The *astringent salts of iron* were first brought into notice in connection with the treatment of the fluxes by the iatro-chemists. It has already been mentioned that the Greek physicians quenched red-hot cylinders of iron in whey or milk for the purpose of giving it astringent and corroborant qualities.‡ Dioscorides praises the use of water or wine, similarly treated, in the fluxes.§ These remedies continued in use for many centuries. J. Crato, indeed, writing of a case of alvine flux treated in 1567, advised that chalybeated drinks should be avoided in dysentery, because they do not astringe, as physicians falsely think, but perturb the belly; his views convinced Plater and Hildanus, but Sennertus stoutly maintained that chalybeates should not be abandoned.‖

Meanwhile Paracelsus and the iatro-chemists had brought into use a host of chalybeate preparations, many of which, especially the various forms of sal Martis, vitriolum Martis, crocus Martis and diversely compounded tincturæ Martis, they boldly employed as astringents in dysentery.¶ So freely were even the more potent of these compounds adminis-

* I note that Surgeon CHARLES SCHÜSSLER—p. 44, *supra*—claimed to have found it useful in the chronic fluxes at hospital No. 6, Nashville, Tenn., during the year 1862; and GORDON—p. 179, *op. cit.*, p. 769, *supra*—in 1869, recommended a solution of alum, with diluted sulphuric acid added, among the remedies to be used in hæmorrhagic dysentery, "where gallic acid fails to check the flux."

† Thus MITSCHERLICH—Bd. I, S. 324, *op. cit.*, p. 765, *supra*—found in rabbits poisoned with alum the intestines inflamed and corroded, (angeätzt.) He states that large or long-continued doses produce the effects mentioned in the text. Yet even he commends it in chronic diarrhœa, and in dysentery after the inflammatory symptoms have subsided—S. 326. ORFILA—T. I, p. 366 *et seq.*, *op. cit.*, p. 699, *supra*—observed as early as 1814 that large doses of alum given to dogs acted as an emetic, but did not produce a fatal result. Subsequently (in 1829) he found that if by ligature of the œsophagus or "by any other cause" vomiting was prevented, death took place in a few hours, and the mucous membrane of the digestive canal was found greatly inflamed. ORFILA found furthermore that after the exhibition of large doses of alum to dogs it could be detected in the urine and in the viscera after death, and hence inferred that it can be absorbed, although from the mode in which it precipitates albumen this would hardly have seemed probable. (I observe that my friend H. C. WOOD—p. 32, *op. cit.*, p. 675, *supra*—was unable to discover the authority for this statement, which, however, is correctly attributed to ORFILA by MITSCHERLICH and NOTHNAGEL in the works cited in this note.) CLARUS—S. 169, *op. cit.*, p. 766, *supra*—contradicted this observation of ORFILA, and declares that after the administration of alum, no trace (keine Spur) of it can be found in the urine. He agreed, however, with MITSCHERLICH as to the irritant and corrosive effect of large doses: he only advised its use in dysentery as an ingredient of clysters. NOTHNAGEL—S. 311, *op. cit.*, p. 746, *supra*—testifies that, given to healthy men in very large doses, alum produces the symptoms of an acute toxic gastro-enteritis. See also STILLÉ—Vol. I. p. 172 *et seq.*, *op. cit.*, p. 711, *supra*, and BUCHHEIM—S. 210 *et seq.*, *op. cit.*, p. 746, *supra*.

‡ See p. 664, *supra*.

§ DIOSCORIDES—Lib. V, Cap. 93, fol. 288, *op. cit.*, p. 623, *supra*: "Vinum aquave in qua candens ferrum sit restinctum, potu cœliacis, dysentericis, lienosis, cholera laborantibus, et dissolutis stomacho auxiliatur." Water thus treated is praised by PLINY, especially in dysentery. PLINY—*Nat. Hist.*, Lib. XXXIV, Cap. 44, Valpy's Ed., London, 1826, Vol. IX, p. 4505: "Calefit etiam ferro candente aqua, multis vitiis, privatim vero dysentericis."

‖ J. CRATO—*Consil.* 201; I quote from L. SCHOLZIUS—*Consil. Med.*, Frankfort, 1598, p. 579. Nevertheless he favored injections of whey in which iron had been quenched: "In recta victus ratione nihil præmittatur, nec detur potus chalybeatus, ut fieri solet. Non enim is astringit, ut falso existimant medici, sed turbat alvum. Serum autem lactis, in quo chalybs extinguitur, per clysterem injiciatur, qui alvum sistit." FELIX PLATER wrote a letter to FABRICIUS HILDANUS—published by the latter p. 670, *op. cit.*, p. 644, *supra*—in support of this view, and HILDANUS, while he confessed—p. 680—that he had for many years given chalybeated water to dysenterics, abandoned the practice, and claims that he succeeded better without it. SENNERTUS devoted a special dissertation to this question—Quæstio VI. *An chalybis usus in dysenteria conveniat*, T. III, p. 189, *op. cit.*, p. 645, *supra*—and not only concluded that chalybeated milk, water and wine may advantageously be used in moderation, but even favored the cautious use of crocus Martis and other chalybeate preparations introduced by the chemists. At the conclusion of this essay he refers to the black color of the stools produced by the chalybeates, and censures the incautious physicians who mistook it for black bile.

¶ Many of these preparations are already discussed in the writings of PARACELSUS. Here we find mention of two varieties of crocus Martis—*De morte rerum nat., Lib. V*, T. II, p. 92, Ed. cited p. 336, *supra*. Here, too, we find the varieties of vitriol discussed—*De sulphure*, Cap. VIII, same Vol., p. 200 *et seq.*—the copper sulphate, regarded as related to the iron sulphate, valuable purgative properties assigned to crude vitriol and colcothar, and the mode of distilling oil of vitriol thence, described. The fifth essence of iron was an ingredient in his specific styptic—*Archidox.*, Lib. VII, same Vol., p. 28—which was so potent that he had known it, administered as a rude jest, to close the anus so completely that mechanical assistance was necessary to open the bowels. It would transcend my limits to discuss at length the teachings of PARACELSUS and the iatro-chemists with regard to the preparations of iron. I confine myself to the citation of a few striking passages: QUERCETANUS—p. 244, *op. cit.*, p. 736, *supra*—described two varieties of crocus Martis, the one astringent, useful in dysentery and lientery, the other aperient, and capable of purging from the spleen and mesentery. OSWALD CROLL—

tered that the frequency with which they provoked diarrhœa gave rise to the belief that certain chalybeates might be used advantageously as purgative medicines.*

The astringent effect of these preparations was chiefly aimed at in the treatment of the alvine fluxes; but with the exception of the iatro-chemists and their disciples, most physicians hesitated to employ them. Degner declared that the use of all chalybeates was to be regarded with suspicion or rejected as noxious, except, perhaps, the tincture of Ludovicus, which, however, he thought useful rather as a corroborant at the close of the disease than as a means of cure.† Partly because his views were shared by others, but chiefly no doubt because preference was given to other astringents, iron was little used in the treatment of the fluxes during the latter part of the last century or the beginning of this; but during the last forty years it has again been brought into use, both with a view to its astringent effects and to improving the quality of the blood in anæmic cases.

For the first of these objects the old use of *sulphate of iron* has been revived, and it has been administered, chiefly in connection with opium, in the later stages of acute dysentery and in the chronic fluxes. It was mentioned by Copland and Vogt, although without particular commendation, among the mineral astringents occasionally employed in dysentery, and has been used also in other fluxes, as, for example, by Leube in intestinal catarrh and by Weiser in the diarrhœa of infants.‡ The *tincture of the chloride of iron*, another old preparation, has also been used to a limited extent for the same purposes.§

But far greater popularity has been attained in modern times by certain other astringent chalybeates. In England the preference has generally been given to *solution of pernitrate of iron*, which was recommended in diarrhœa by Kerr, (1832,) and in chronic fluxes by Graves, Neligan and Maclean, as well as by Adam in this country.‖ In France the favorite

---

pp. 342–50, *op. cit.*, same page, *supra*—had an essentia croci Martis which cured diarrhœa and dysentery as well as external and internal hæmorrhages of all kinds. ANDREAS LIBAVIUS—*Appendix necessaria Syntagmatis Arcanorum Chymicorum*, Frankfort, 1615—wrote at length on the preparations of iron. He claimed that water, wine, vinegar and the like, in which iron or steel had been extinguished, were undoubtedly beneficial in the alvine fluxes, brought forward authorities in favor of this view and combated objections—*Syntag. Arcan. Chym.*, Pars III, Lib. I, Cap. 10, p. 20, *op. cit.* He treated in extenso of crocus Martis—Lib. V, Cap. 22, p. 198—of which there are several varieties, differing not only in appearance but in therapeutical effects: there is a tincture of crocus Martis possessed of powerful astringent properties—p. 200; see also his remarks on sal Martis—Lib. VI, Cap. 22, p. 254—and tinctura Martis—Lib. VIII, Cap. 16, p. 401—which cures dysenteries. The curious reader will find a good deal of information with regard to the preparations of iron introduced by the iatro-chemists in the work of MANGETUS—T. I, p. 917 *et seq.*, *op. cit.*, p. 736, *supra*; the *Dictionary* of JAMES—art. *Mars.*, *op. cit.*, p. 690, *supra*; the *Dispensatory* of QUINCY—p. 253 *et seq.*, *op. cit.*, p. 730, *supra*, or Part II, p. 77 *et seq.*, *op. cit.*, p. 734, *supra*; and the work of C. ALSTON—*Lectures on the Materia Medica*, London, 1770, Vol. I, p. 135 *et seq.* It is sufficient for our present purpose to say that the various forms of crocus Martis represented the sesquioxide of iron in various degrees of purity; the sal Martis or sal chalybis was the artificially prepared sulphate of iron; the term vitriolum Martis was applied to the same, as well as to the native sulphate, while the tincturæ Martis were prepared in various ways from the crocus or other preparations, and were of the most various strength.

* This view was already formulated by PARACELSUS—*De Sulphure*, *loc. cit.*, last note—and was discussed by many of the iatro-chemists and others. JAMES—*loc. cit.*, last note—wrote as late as 1745: "Physicians now acknowledge a twofold virtue in iron, one aperient, the other astringent;" and adds: "Some attribute an aperient virtue to some preparations of iron, and an astringent virtue to others; but the truth is, all these preparations are both astringent and aperient, though not in the same degree."

† DEGNER—Cap. V, § 18, p. 273 *et seq.*, *op. cit.*, p. 625, *supra*. The tinct. vitriol. Martis Lud. of which he speaks was perhaps the solution of sulphate of iron in distilled vinegar described by D. LUDOVICUS—*De pharm. modern. seculo applicanda Diss. I*, (1671,) Opera Omnia, Leipsic, 1712, p. 517—perhaps one of the tinctures described in his *Diss. de vol. salis tartari*, (1667,) *op. cit.*, p. 856, among which I note already a solution of flores Martis in spiritus salis, that is substantially a solution of chloride of iron.

‡ COPLAND—Vol. I, p. 730, *op. cit.*, p. 682, *supra*; VOGT—S. 206, *op. cit.*, p. 645, *supra*. LEUBE—S. 276, *op. cit.*, p. 750, *supra*—after declaring that experience has shown the beneficial action of astringents in this disease, enumerates, among those most commonly used, acetate of lead, nitrate of silver, tannin, alum, sulphate of iron, (10 to 20 centigrammes per dose,) and solution of the sesquichloride of iron, (5 to 8 drops per dose.) K. WEISER—*Ueber die Behandlung des Durchfalls bei Säuglingen*, Wiener Med. Wochenschrift, 1871, S. 849.

§ This tincture was devised not long after the discovery of muriatic acid by GLAUBER—see note ‡, p. 706, *supra*. The earliest direction for its preparation with which I am acquainted was given by BATE—I cite from W. SALMON—p. 238, *op. cit.*, p. 730, *supra*—who called it *tinctura Martis aurea*. He directed an ounce of crocus Martis to be infused in four of spirits of salt, and four ounces of rectified spirits of wine to be added. As late as 1850 the U. S. Pharmacopœia still directed this preparation to be made by treating the subcarbonate of iron with muriatic acid and adding alcohol.

‖ WM. KERR—*On the use of the persesquinitrate of iron in diarrhœa, and some other affections of the mucous membrane of the alimentary canal*, Edinburgh Med. and Surg. Jour., Vol. XXXVII, 1832, p. 99; *Additional evidence of the efficacy of the persesquinitrate of iron in curing diarrhœa*, Glasgow Med. Jour., Vol. V, 1832, pp. 215 and 375; *On the medicinal effects of the persesquinitrate of iron*, Monthly Jour. of Med. Sci., Vol. VIII, 1848, p. 784. R. J. GRAVES—*Clinical Lectures*, Lect. XII, Lond. Med. and Surg. Jour., Vol. VII, Part 2, 1835, p. 513, and *Clinical Lectures*, 2d Ed., London, 1848, Lect. LII, Vol. II, p. 226; J. M. NELIGAN—*Medicines, their uses, &c.*, American reprint, New York, 1844, p. 65. MACLEAN—Vol. I, p. 124, *op. cit.*, p. 657, *supra*—in speaking of the treatment of chronic dysentery, writes: "My favourite remedy, particularly in men returning from tropical regions, anæmic from loss of blood and the depraving influence of malaria, is the solution of the pernitrate of iron, which I use at Netley very freely, and often with the happiest effect." T. C. ADAM—*On the remedial powers of the persesquinitrate of iron*, Amer. Jour. of the Med. Sci., Vol. XXIV, 1839, p. 61.

preparation has been the *perchloride of iron*, to which attention was directed in 1856 by Deleau, as a remedy in blenorrhagic affections of the mucous membranes. The following year Pize reported that it had been successfully used in diarrhœa by several other physicians as well as himself. It has been employed in dysentery by Bourguignon, Baudon, Savignac, Barrallier and others.* Savignac and Barrallier went so far as to express the opinion that it is the only mineral astringent admissible in this disease. Méran, indeed, found that in two cases it provoked severe colic, and had to be abandoned; yet even he regarded it as admissible in chronic fluxes.† The *persulphate of iron* has also had its advocates, though it has been less generally employed.‡

Several of these preparations of iron were occasionally used in the treatment of chronic fluxes by military surgeons during our civil war; the sulphate was least frequently employed; the tincture of the chloride and the persulphate had each more numerous advocates, some of whom even claimed for them a place among the most efficient remedies for these disorders. But the great majority of medical officers avoided this use of the salts of iron, and a few, after fairly trying them in such cases, abandoned them because they did not obtain satisfactory results.§ I suspect that had these salts been more generally used for their astringent effects, the complaints of failure would have been still more numerous.

Abundant testimony with regard to inconveniences and even injurious effects from the continuous use of notable doses of the astringent salts of iron has been collected by the systematic writers on therapeutics. When the quantity administered is sufficient to produce

* DELEAU—*Mémoire sur l'action du perchlorure de fer dans certaines maladies*, La France Méd. et Pharm., 1856, p. 251—declared: "Que le perchlorure de fer est un modificateur des tissus vivants, mais surtout modificateur thérapeutique des membranes muqueuses dans les blennorrhagies et dans les leucorrhées;" moreover, he asserted that there is no danger in its internal use. The following year L. PIZE—*Mém. sur l'action thérapeutique et physiologique du perchlorure de fer*, Moniteur des Hopitaux, T. V, 1857, p. 142—stated that the perchloride of iron had been found efficacious in certain diarrhœas by several other physicians as well as himself. A dispute as to the priority ensued between him and DELEAU—same Vol., pp. 159 and 223. In June, 1857, DELEAU read a memoir on this salt to the Academy of Sciences—same Vol., p. 677—in which he maintained the conclusions of his first paper. In his *Études cliniques sur le perchlorure de fer*—same Vol., p. 2064—he published two cases of dysentery successfully treated with this preparation by BOURGUIGNON, de Béthisy-Saint-Pierre, (Oise.) A. BAUDON—*De l'emploi du perchlorure de fer dans la dyssenterie*, Bull. Gén. de Thér., T. LXI, 1861, p. 464—employed "ce précieux médicament" successfully in twelve cases of dysentery, giving 12 to 30 drops daily in 180 grammes of sweetened water, divided into convenient doses, and using the drug also in enemata. SAVIGNAC—p. 400, *op. cit.*, p. 620, *supra*—admits, however, that he found it far from realizing theoretical hopes, and commends it chiefly in hæmorrhagic cases. BARRALLIER—p. 771, *op. cit.*, p. 603, *supra*. For other favorable testimony I may refer to the statement of its beneficial use in the Vienna hospital, in 1864, in dysenteries passing into a chronic condition, in the Aerztlicher Bericht des k. k. allg. Krankenhauses zu Wien, 1864, Vienna, 1865, S. 58, and a lecture of C. PAUL—*Leçon sur la dysenterie*, Gaz. Méd. de Paris, T. XXV, 1870, p. 536—who commended it especially in hæmorrhagic dysentery. It has also been advised in the treatment of choleriform diarrhœa by DELEZENNE—*Perchlorure de fer contre la diarrhée*, Gaz. des Hopitaux, 32e année, 1866, p. 450—and LAWSON is said to have used it with advantage in summer diarrhœas resulting from the use of impure water or unwholesome fruit: see an article entitled *Diarrhœa and its treatment at the London hospitals*, Med. Times and Gaz., Vol. II for 1868, p. 122.

† MÉRAN—*loc. cit.*, p. 676, *supra*—reported to the Bordeaux Medical Society, Nov. 7, 1859, that in the two cases of dysentery in which he tried the use of raw meat he also tried perchloride of iron in the later stages, but the colics, which had subsided, briskly returned, and he had to abandon it. He concluded that the remedy should not be used except in chronic cases, or at least after the acuteness of the inflammatory accidents had subsided; in the indolent dysentery of children it acted better. DUPUY stated to the same meeting that a patient, to whom he had given the perchloride, suffered from vomiting, but that on giving it more dilute it was well borne, (parfaitement tolerée.)

‡ Monsel's salt: see MONSEL—*Nouveau per-sulfate de fer soluble*. Jour. de Méd. de Bordeaux, 1857, p. 291.

§ See, on this subject, the views of the reporters in Section II of this chapter. The sulphate of iron was praised by SCHÜSSLER—p. 44, *supra*—who, however, used indifferently the chloride and the persulphate. On the other hand, BIGELOW—p. 83—reports that he used the sulphate without effect. The tincture of the chloride of iron was employed by MCDONALD—p. 78; BROWN—p. 81; and BRADT—p. 100. The persulphate of iron was used by DE BRULER—p. 42; B. WOODWARD—p. 51; BRETZ—p. 80; WALTON—p. 88; and COOPER—p. 93: WELCH—p. 96—even commended this salt, in combination with opium, in the treatment of acute dysentery. See also the paper of E. L. JONES, (Asst. Surgeon 53d Wisconsin,)—*On diarrhœa as seen in the camps*, Chicago Med. Jour., Vol. XXII, 1865, p. 246—who praises the use of the tincture of the chloride of iron in camp diarrhœa, and that of J. R. LOTHROP—*Report of the Buffalo General Hospital*, Buffalo Med. and Surg. Jour., Vol. V, 1866, p. 21—who gives the following testimony with regard to the treatment of diarrhœa in that hospital: "The astringent preparations of iron were more employed than any other medicines, and particularly the muriated tincture of iron. Continued for a long time more benefit was perceptible from it than from any other medicine." On the other hand, the persulphate of iron has been praised by J. DAVIS—*Hospital reports. Commercial hospital. On the use of persulphate of iron in diarrhœa*, Cincinnati Lancet and Observer, Vol. V, 1862, p. 597—who reported six cases of chronic diarrhœa in which it was used: four recovered, one left the hospital in an improved condition and one died. O. C. GIBBS, (late Surgeon 21st New York,)—*Persulphate of iron in camp diarrhœa*, same Jour., Vol. VI, 1863, p. 462—praises the same remedy, remarking: "I had every reason to be pleased with the result. At first the remedy was used in one-grain doses, but those were soon increased to two and three, and, in some cases, as high as five-grain doses. I never saw harm result from its use." He gave it combined with opium. In the tract of STILLÉ—p. 379, *op. cit.*, p. 650, *supra*—I find the following directions for the use of iron in chronic dysentery: "Finally, when anæmia complicates the disorder of the bowel, and bitter vegetable preparations fail to invigorate digestion, iron should be prescribed, and particularly the preparations which possess a marked astringency, as the muriated tincture, the persesquinitrate, and the perchloride." PENROSE, however—p. 45, *supra*—reports that he employed the salts of iron in chronic fluxes at Satterlee hospital "without satisfactory results;" which corresponds with the experience of BIGELOW—cited *supra*—as to the use of the sulphate.

temporarily a recognizable restraining effect upon the stools they perturb the digestive processes, and if their use is persisted in they are prone to irritate the intestinal canal. Under such circumstances they often produce intestinal catarrh, manifested by gripings and diarrhœa, even in those whose bowels were healthy when the treatment was begun.* In the fluxes still smaller doses will be found to irritate the intestines, and if by their means a temporary arrest of the discharges be sometimes effected, a relapse is apt to follow, with increased violence of all the symptoms.

I do not, however, feel any doubts with regard to the usefulness of chalybeate preparations, when prudently administered, for the purpose of increasing the proportion of the red blood corpuscles in anæmic conditions concomitant with the advanced stages of the chronic fluxes; but I cannot agree with Stillé, that for this purpose the astringent salts should be selected.† On the contrary, I think that preference should be given to those mild chalybeates which experience has shown are least likely to perturb the stomach and bowels. The phosphate, the lactate, the oxalate and the sesquioxide are better suited for this purpose than the more potent astringent salts; and even these preparations should be administered in small doses, as little as possible in excess of the quantity that can be absorbed. The citrate of iron and quinia often proves an excellent combination in these cases.

The *sulphate of copper*, also, was brought into use in the treatment of the fluxes by Paracelsus, who embraced it along with iron sulphate under the head of vitriol, which he declared to be a peculiar genus, diverse in its virtues from all other salts, and attributed to it marvellous medicinal powers, asserting that rightly used it was worth more than all the drugs of Greece, Egypt or India. He ordered vitriol to be given in dysentery in such doses that it should cause both vomiting and purging,‡ and it is by no means strange that this reckless practice should have found few imitators. Near the middle of the last century Geoffroy wrote that copper is little used internally in medicine, but belongs to the poisons; it produces pains and colics in the stomach and bowels, enormous vomitings, frequent and vain desire to go to stool and intestinal ulceration.§ On the other hand, Alston, having swallowed by direction of an empiric, half a drachm of sulphate of copper and escaped serious consequences, declared his belief that copper is no more a poison than iron, and that it cannot cause ulcerations of the intestines, but would rather cure them.‖ This hint, however, did not attract attention at the time, and it is only in the present century that sulphate of copper has been brought into common use in the chronic fluxes.

Although by no means the first to employ it for this purpose, Elliotson deserves the credit or blame of having introduced it into general notice. He gave it in chronic dysen-

* See the account of these inconveniences in the works of MITSCHERLICH—Bd. I, S. 349 *et seq.*, *op. cit.*, p. 765, *supra;* CLARUS—S. 269 *et seq.*, *op. cit.*, p. 766, *supra;* NOTHNAGEL—S. 428 *et seq.*, *op. cit.*, p. 746, *supra;* and BUCHHEIM—S. 215 *et seq.*, *op. cit.*, p. 746, *supra.* The same authors may be consulted on the general question of the therapeutical action of iron.

† See note §, last page.

‡ PARACELSUS—*De sulphure, Cap.* 8, T. II, p. 200 *et seq.*, *op. cit.*, p. 336, *supra.* It is clear from his remarks, *De speciebus vitrioli.* that he preferred an impure vitriol, composed only in part of sulphate of copper, for while he insists on its depositing copper on iron as an alchymical test of its nature, (which he interpreted as a transformation of iron into copper by the action of vitriol,) he remarks that a vitriol which is blue throughout, without intermixture of other colors, is not so excellent in medicine. As to its use in dysentery, &c., he wrote: "Per vitam militarem ex immoderatione frequenter etiam accidit, ut prunellæ, febres, dysenteriæ, et alia oriantur. In his morbis omnibus summum est præstantissimumque remedium purgatio per vitriolum, quod tecte et allegorice vocitarunt Gryllum." The dose should be six times as much as can be taken on the point of a knife; if it do not operate, this should be repeated a second or even a third time, but not oftener. It may be given to the feeble in wine or water, but to robust men of stronger bowels (durioris alvi) in alcohol, (vino sublimato): "Ita datum radicitùs expurgat per superiora et inferiora." I should think it would.

§ GEOFFROY—*Tractatus de materia medica*, 1741; I cite the French translation of A. BERGIER, T. I, Paris, 1743, p. 519.

‖ C. ALSTON—Vol. I, Lect. XX, Sect. 2, p. 128, *op. cit.*, p. 772, *supra:* "I was, when about eighteen, persuaded by a lady doctress to take vitrioli cærulei 3ss dissolved in a glass of water, for a vomit; with which, as she said, she had done much good to many. A large dose indeed! But as I don't remember to have stood in need of it, and being difficultly moved, I vomited but little, and was rather the worse than better for it. Its taste continued with me several days. Hence it is no poison more than iron; and cannot cause intestinorum exulcerationes, but would rather cure them." This is an excellent example of the *non sequitur*.

tery, combined with opium, in pill form; and, because it often nauseated, endeavored to force the stomach to retain it by the sedative influence of hydrocyanic acid.* This practice speedily found imitators. Pereira not only declared that sulphate of copper often succeeded where vegetable astringents failed, but went so far as to employ it in the chronic diarrhœas of infants in the dose of one-twelfth of a grain.† Raleigh praised it above all other astringents in chronic dysentery, but advised that the dose should not exceed one-sixth of a grain.‡ Joseph Brown also employed it in these cases, but only claimed temporary benefit from its use.§ We find it named as an eligible mineral astringent in chronic dysentery in the works of Canstatt, Morehead, Aitken and others.‖ It was employed for this purpose by several medical officers during our civil war,¶ and I myself used it to some extent, but ultimately abandoned it, because, although I seldom exceeded the eighth of a grain at a dose, and guarded it with opium, it seemed often to aggravate the flux instead of checking it. So, too, Maclean states that he uses it with a sparing hand, and only under the pressure of necessity, although he has not defined the necessity to which he refers.**

Wood taught that sulphate of copper proves useful in the chronic fluxes less in consequence of its astringency than because of a supposed stimulant and alterative influence upon the ulcerated surfaces, similar to that it exerts upon old, indolent ulcers when applied externally.†† The same opinion appears to have been entertained by Fox, who states that he has found it, combined with opium and quinia, especially useful in those chronic diarrhœas in which from the symptoms he believed intestinal ulceration to exist.‡‡

But we possess no evidence to show the correctness of this speculation, and it seems highly improbable that in the doses ordinarily given the copper salt reaches the ulcerated surface in sufficient quantity to act in this way. It is much more probable that the more minute doses owe whatever power they seem to exercise in restraining the bowels to the opium with which they are combined; and doses of the sixth of a grain or more, repeated several times daily, should be regarded with suspicion. They will often be found to produce nausea, vomiting or other gastric disturbances, and to aggravate the flux instead of restraining it. It is well known that in large doses the sulphate, like the other soluble salts of copper, is a violent irritant poison. The continuous use of food contaminated by unclean

* J. ELLIOTSON—*On the use of the sulphate of copper in chronic diarrhœa*, Med.-Chirurgical Transactions, Vol. XIII, Part 2, 1827, p. 452—thus relates the circumstances under which he first used this medicine, in the year 1824: "Mr. Henry South, one of the pupils, mentioned to me that two cases of the successful exhibition of sulphate of copper and opium in diarrhœa, had recently been related in the Physical Society of Guy's Hospital, and I instantly resolved to profit by his information, and prescribed half a grain of the sulphate of copper twice a-day, with two grains of opium." In this paper he stated that he had used this combination successfully in St. Thomas's hospital for two years and a half, and that "the dose usually borne and required varies from a grain and a half to three grains," which "may be taken for an indefinite time without any fear of constitutional ill effects." He admitted that "it certainly has a tendency to produce vomiting and griping," and therefore gave it in pill form, combined with opium. But even this did not always succeed, for we find him subsequently—*Lectures on the theory and practice of medicine*, The London Medical Gazette, Vol. XII, 1833, p. 557—directing that one to four drops of hydrocyanic acid should be given with each dose, if the opium and copper produce sickness of the stomach. Here, too, in his eagerness to show that no constitutional injury is done by the long continued use of the drug, we find the statement, "I have known a patient take it for three years, for a peculiar kind of diarrhœa, without any such result;" which does not say much for the efficacy of the remedy. See also his account of a case of chronic dysentery successfully treated with sulphate of copper and opium in an earlier number of the same journal—*St. Thomas's hospital. Clinical lecture*, Vol. VIII, 1831, p. 379—and, for a summary of his views on this subject—p. 1060, *op. cit.*, p. 267, *supra*. It will be observed that he still insists upon the use of hydrocyanic acid to quiet the stomach.

† PEREIRA—Vol. I, p. 759, *op. cit.*, p. 746, *supra*. Sulphate of copper has also been praised in the diarrhœa of teething infants by D. M. EISENMANN—*De l'emploi du sulfate de cuivre oplacé comme traitement de la diarrhée occasionnée par la dentition*, Bull. Gén. de Thér., T. LVI, 1859, p. 561.

‡ RALEIGH—p. 112 *et seq.*, *op. cit.*, p. 712, *supra*. § J. BROWN—Vol. I, p. 727, *op. cit.*, p. 715, *supra*.

‖ CANSTATT—Bd. I, S. 526, *op. cit.*, p. 717, *supra;* MOREHEAD—p. 304, *op. cit.*, p. 657, *supra;* AITKEN—Vol. II, p. 659, *op. cit.*, p. 647, *supra*.

¶ See, for example, in Section II, the reports of DE BRULER—p. 42, *supra;* HOLSTON—p. 66; WALTON—p. 88; COOPER—p. 93; and WELCH—p. 96. J. B. BURNET—*Case of chronic dysentery*, The Med. and Surg. Reporter, Vol. XVII, 1867, p. 95—reports a case of chronic dysentery contracted during the war, which was treated in Bellevue hospital, among other remedies, with sulphate of copper and opium, and states that this was the remedy found most efficacious in such cases during his residence in that hospital.

** MACLEAN—Vol. I, p. 124, *op. cit.*, p. 657, *supra*. †† G. B. WOOD—*A Treatise on Therapeutics*, 2d Ed., Phila., 1860, Vol. I, p. 415.

‡‡ T. FOX—*On the curability of chronic diarrhœa*, The Med. Archives, (St. Louis,) Vol. IV, 1870, p. 134: "When there is ulceration of the bowels, as indicated by the retracted abdominal parietes, tenderness on pressure, the presence of black blood in the stools, the contracted, dry, and fissured tongue, and pinched, hard, anxious expression of countenance, the sulphate of copper in small doses, combined with quinine and opium, serves a better purpose, as a continuous treatment, than any formulæ which I have used"—p. 136.

copper vessels gives rise to dangerous and sometimes fatal gastro-enteritis.* It is doubtful whether such doses of the sulphate as were recommended by Elliotson can long be given with greater impunity; whether they do not more frequently injure than benefit.†

The *sulphate of zinc*, employed as an emetic in dysentery by Angelus Sala, and used in combination with alum in the same disease by Moseley,‡ has also been administered in small doses combined with opium in the treatment of chronic fluxes.§ Almost equally as objectionable as copper, there is still less evidence that it is really useful.

The *oxide of zinc* has been more extensively used, particularly in chronic fluxes. James Adair, in a letter which Duncan published in 1785, reported its beneficial effects in a form of cachectic diarrhœa he had observed among the negroes of Antigua.‖ Hendy,¶ in a work published in 1784, mentioned the success with which he had administered it to obstinate cases of habitual diarrhœa while residing in the Barbadoes colony. This use of the oxide of zinc was mentioned with approval by Copland, but Stillé, who referred to it in 1860, prudently remarked that the instances of its alleged efficiency were too few to inspire any confidence in its use.** Penrose prescribed it with supposed advantage at Satterlee hospital during the civil war; he gave it in ten-grain doses along with an equal quantity of powdered nutmeg, and erroneously supposed the remedy to be a novel one.†† Within the last ten years the advocates of this medicament have become more numerous.

---

* For an account of the symptoms of poisoning from large doses of sulphate of copper, the reader is referred to the works on toxicology. The accidents resulting to healthy individuals from the contamination of the food with copper derived from unclean copper cooking utensils have been well described by T. MOORE—*Obs. on acute inflammation of the stomach and bowels, produced by the intermixture of verdigris with the food*, The Lancet, 1846, Vol. I, p. 412—who traced to this cause a disease, "which, in its symptoms, course, and termination, presented many of the characteristic features of acute idiopathic dysentery," that broke out among some coolies returning from British Guiana to Calcutta. Post-mortem examination in the fatal cases disclosed severe inflammatory lesions in the stomach and intestines.

† CLARUS—S. 779, *op. cit.*, p. 766, *supra*—testifies that while minute doses of the copper salts disturb the digestion, they appear to produce no essential effect upon the intestine, but that in larger doses they produce greenish, and in still larger bloody, diarrhœa. According to NOTHNAGEL—S. 291, *op. cit.*, p. 746, *supra*—doses of .2 to .3 grammes (three to four and a half grains) almost always produce vomiting, sometimes also diarrhœa, when given to healthy individuals. BUCHHEIM—S. 291, *op. cit.*, p. 746, *supra*—speaking of the use of medicinal doses of sulphate of copper in chronic fluxes, says they do not appear to possess any advantage over numerous other drugs, and adds that larger doses readily provoke diarrhœa.

‡ ANGELUS SALA—*Ternarius Bezoardicorum*, Cap. X, (Leyden, 1616;) I cite Opera Medico-Chymica, Frankfort, 1647, p. 560. He gave from one to two scruples with syrup of quinces and betony water, flavored with cinnamon: compare RIVERIUS—*loc. cit.*, p. 689, *supra*. MOSELEY—see p. 770, *supra*.

§ The use of sulphate of zinc as an astringent in chronic fluxes is mentioned by CLARUS—S. 772, *op. cit.*, p. 766, *supra;* NOTHNAGEL—S. 286, *op. cit.*, p. 746, *supra;* H. C. WOOD—p. 41, *op. cit.*, p. 675, *supra*. and others. NOTHNAGEL remarks: "Dass es beim Darmcatarrh adstringirend wirken könne, ist richtig, indess besitzen wir zu diesem Zweck andere Mittel, die energischer sind, ohne die gleichzeitigen Nachtheile des Zinkvitriol zu haben."

‖ J. ADAIR—*loc. cit.*, note †, p. 770, *supra*—used the native calamine: "*Lapis Calaminaris*. From five grains to one scruple for a dose, with one or other of the adjuncts mentioned under the preceding article, is a powerful astringent in the diarrhœa cachectica:" the adjuncts mentioned are spermaceti, gum Arabic and opium. In the previous paragraph it is explained that the author bestowed the term diarrhœa cachectica upon a diarrhœa which prevailed among the negroes of Antigua the year before. There is no date to this letter, and the volume of DUNCAN'S *Commentaries*, in which it is published, refers to the years 1783–84. I note that H. PUYGAUTHIER—*De l'emploi de l'oxyde de zinc dans le traitement de la diarrhée*, Paris Thesis, No. 250, 1874, p. 6—states that oxide of zinc was first employed in diarrhœa about the year 1781 by ADAIR and J. HENLY, and cites in support of this statement J. F. GMELIN—*Apparatus Medicaminum*, Gottingen, 1795–96, a work which I greatly regret is not in our library. If, however, GMELIN is correctly cited, there is a misprint or mistake in the name of HENLY, the person referred to being unquestionably JAMES HENDY: see next note.

¶ JAMES HENDY—*A treatise on the glandular disease of Barbadoes: proving it to be seated in the lymphatic system*, London, 1784, Part I, Sect. II, p. 86, note: "Flowers of zinc, in my opinion, are a most important article in medicine. I have made trial of them, in a variety of cases, with the greatest advantage to the patient." He specifies epilepsy, hysteria, locked jaw, putrid fevers attended with spasms, intermittent fevers, nervous fevers, &c., and adds: "I have given them, joined with opium, in the habitual diarrhœa, when bark and opium have been ineffectually tried."

** COPLAND—Vol. I, p. 535, *op. cit.*, p. 682, *supra*—in speaking of the use of the mineral astringents, "in several of the forms of diarrhœa, particularly the chronic," wrote: "The sulphate and oxide of zinc are also useful, especially when combined with rhubarb, or myrrh, or the balsams, or terebinthinates," and he cites a formula from DE HAEN for a combination of oxide of zinc with calcined magnesia and powdered columbo as useful for this purpose: see appendix of formulæ, same Vol. STILLÉ—Vol. II, p. 172, *op. cit.*, p. 711, *supra:* "Oxide of zinc is also reported to have cured whooping-cough, spasmodic asthma, intermittent fever, and chronic dysentery, but the instances of its alleged efficacy are too few to inspire any confidence in its use in these affections." This passage also occurs in the first edition of the same work, Philadelphia, 1860, Vol. II, p. 232.

†† PENROSE—p. 45, *supra:* "The remedies which have been most positive in their results, after the acids and opium, have been nutmeg and the oxide of zinc, and the author of this communication claims originality in using them in the disease under consideration." Nothing is easier than to make such claims, nothing harder than to defend them. We have just seen that the use of oxide of zinc in the chronic fluxes dates back to the last century. As for the nutmeg, it was already commended as an aromatic and astringent by AVICENNA, who declared that it eased pain, (confert doloribus,)—so that my friend is not even original in his notion that nutmeg is an anodyne—vide *infra*—and strengthened (confortat) the liver, spleen and stomach—Lib. II, Tract. 2, Cap. 502, p. 362, *op. cit.*, p. 632, *supra*. It figures as an ingredient in a formula recommended by him for the cure of chronic fluxes dependent on ulceration of the bowels—Lib. III, Fen. 16, Tract. 2, Cap. 3, p. 821, *op. cit.* HILDANUS—Cap. X, p. 686, *op. cit.*, p. 644, *supra*—adopted these views, and assigned to nutmeg a high place among the simples by which the bowels may be restrained in dysentery. The only originality in the method of PENROSE must therefore lie in giving the two remedies together, or perhaps in the following fanciful explanation of their *modus operandi:* "The nutmeg was directed as an aromatic and anodyne, conveyed most probably to the ulcerated surface and there producing its beneficial effects. The oxide of zinc was given with the view of having it carried directly to the seat of disease, being perfectly acceptable to the stomach, and if acted on by the acids of the intestines only made more astringent, while its ordinary effects were mild astringency, tonic, and, perhaps, anodyne or sedative effects locally"—*loc. cit.*

Curran praised it in chronic fluxes; Brakenridge, Mackey and Tyson in infantile diarrhœa;* while Gubler, and following him Bonamy, claim to have given it with excellent results in ordinary acute diarrhœa as well as in chronic cases.

But even Gubler admits, as an occasional inconvenience, that the drug sometimes disturbs the stomach and provokes vomiting;† and the experience of those who formerly employed it in the treatment of epilepsy shows that considerable doses, long administered, can hardly be regarded as innoxious. They are prone to disturb the digestive functions, to provoke nausea, vomiting, sometimes diarrhœa, and to impair the general health.‡ Similar effects were observed by Werneck from the administration of the drug to healthy persons, and by Michaelis in experiments on animals; the latter found on dissection ulceration of the stomach and bowels.§ The long continued employment of the oxide of zinc in the fluxes must therefore be regarded with distrust.

The employment of *nitrate of silver* in these diseases dates back to Paracelsus, who lauded the virtues of silver in restraining profluvia, as well as in the cure of pains of the head, the spleen and the liver; but he modified the caustic properties of the silver salt by treating it with crude tartar before using it in the fluxes.‖ Angelus Sala, indeed, who, in 1614, published a process for preparing pure nitrate of silver in crystals for medicinal use, declared that it might be given internally in the dose of five to eight grains, that it purged without producing pains in the stomach and belly, cured epilepsy, all sorts of catarrhs and dropsy. But it is doubtful whether this account was drawn by Sala from the use of the pure nitrate or of his *magisterium lunæ dejectorium*,¶ in which the acrimony of the silver salt was mitigated by adding nitrate of potash to it and cautiously heating at a tempera-

* J. W. CURRAN—*Oxide of zinc as a therapeutic agent*, The Lancet, 1868, Vol. II, p. 538: "Chronic diarrhœa and dysentery are best and most speedily treated by the oxide of zinc." D. J. BRAKENRIDGE—*On oxide of zinc as a remedy for the diarrhœa of infancy and childhood*, The Med. Times and Gazette, 1873, Vol. I, p. 164; E. MACKEY—*Oxide of zinc in infantile diarrhœa*, The British Med. Jour., 1873, Vol. II, p. 39; TYSON—*loc. cit.*, p. 760, *supra*.

† The success of this drug in the hands of GUBLER is reported by PUYGAUTHIER in the thesis cited note ‖, last page. In illustration of its benefits 14 cases are detailed, observed at the Beaujon hospital. They were chiefly cases of phthisis with consecutive diarrhœa, which appeared to be checked by the oxide given in the dose of 4 grammes, or sometimes 3.50 grammes of oxide of zinc with .50 of bicarbonate of soda; the latter added on account of the nausea and vomiting sometimes produced by the oxide when given alone. See also A. GUBLER—*Commentaires Thérapeutiques du Codex Medicamentarius*, 2me Éd., Paris. 1874, p. 586—who explains that he was led to employ this remedy on account of the high price of subnitrate of bismuth. It may be given in serous and bilious diarrhœas provided it is used in large doses, for he admits that in small doses it may be transformed in the stomach into soluble salts of zinc, which act as emeto-cathartics; but even in large doses he also admits that it sometimes produces vomiting and diarrhœic stools. BONAMY (of Nantes)—*Du traitement des diarrhées rebelles par l'oxyde de zinc*, Bull. Gén. de Thér., T. XCII, 1877, p. 251—reported success from the administration of GUBLER'S combination of oxide of zinc and bicarbonate of soda to a number of cases of obstinate diarrhœa observed during 1876 at l'Hôtel-Dieu de Nantes. The same cases, with some additional ones, are reported by P. JACQUIER—*De l'emploi de l'oxyde de zinc dans la diarrhée*, Paris Thesis, No. 118, 1878—who, however, admits—p. 12—that the drug occasionally produces nausea and vomiting.

‡ Already A. G. RICHTER—*Die Spec. Therapie*, (herausgegeben von G. A. Richter,) 3te Aufl., Bd. VII, Berlin, 1824, S. 695—stated that when oxide of zinc is given to epileptics it frequently produces gastric disorder, and, especially in the case of children, unexpected vomiting. He even went so far as to suggest that it was by producing counter-irritation in the stomach that it relieved the cerebral disease. BUSSE—*Langsame Vergiftung durch Zinkblumen, bei der Kur einer inveterirten Epilepsie*, Wochenschritt für die gesammte Heilkunde, Jahrg. 1837, S. 302—reported the case of a man who took daily, on an average, over 20 grains for epilepsy until he had consumed 3.246 grains. It produced symptoms of chronic poisoning, manifested by marasmus, œdema of the lower extremities, incipient ascites and mental feebleness approaching to idiocy; but there appears to have been constipation in this case instead of diarrhœa; the symptoms disappeared after the withdrawal of the drug. Even T. HERPIN—*Du Pronostic et du Traitement Curatif de L'Épilepsie*, Paris, 1852—who was most enthusiastic as to the good effects of zinc oxide in epilepsy, and who declared: "Qu'il constitue un remède parfaitement innocent, qui peut être donné jusqu'à 6 grammes par jour sans autre inconvénient que des malaises passagers, et qui peut être continué impunément pendant un temps en quelque sorte illimité"—p. 565—had to admit the frequent occurrence of nausea and the occasional development of vomiting and diarrhœa among those subjected to this treatment—p. 558 *et seq.* In the hands of DELASIAUVE—*Traité de L'Épilepsie*, Paris, 1854—these accidents were found to be more serious, and he often had to suspend the treatment, as much on account of the persistent diarrhœa as of the disgust inspired by it: "Tant à cause d'une diarrhée persistante que du dégoût qu'il inspirait"—p. 375.

§ WERNECK—*Erscheinungen, welche das Zincum oxydatum album oder Flores Zinci bey gesunden Menschen hervorbrachte*, Med.-chirurg. Zeitung, 1831, Bd. III, S. 317—gave zinc oxide to fifteen healthy persons besides himself, and found it to produce gastric uneasiness, vomiting, fever, thirst and other disturbances. A. MICHAELIS—*Die physiologischen Wirkungen des Zinkoxyds*, Archiv für physiolog. Heilk., Jahrg. X, 1851, S. 109 *et seq.*

‖ PARACELSUS—*De Præparationibus*, Lib. I, Tract. 5, Vol. II, p. 82, *op. cit.*, p. 336, *supra*. I give his formula for preparing silver for use in the profluvia: "℞. Argenti limaturæ 3j. Reduc in calcem per aquam Regis. Hujus calcis ℞. 3ij. tartari crudi 3iiij. Reduc ad quartum gradum reverberationis cum extractione Alcali." The aqua regis he then directs to be prepared by distilling nitrum aluminis with vitriol. The product was administered in solution, and said to be especially indicated if the stools were bloody, (Si profluvium rubeum exit, signum est, profluvium cohibitum iri.) I suppose much of the silver nitrate was reduced by heating it with the tartar, and what the strength of the resulting preparation was would be difficult now to say in the absence of more precise details as to the degree of heat employed.

¶ ANGELUS SALA—*Septem planetarum terrestrium spagyrica recensio*, (Amsterdam, 1614,) Opera, p. 194 *et seq.*, Ed. cited p. 776, *supra*—made nitric acid, which he called aqua fortis, in which he dissolved silver purified from copper by means of lead: the solution was evaporated and carefully fused. He called the product *magisterium argenti, crystallum Dianæ, catharticum lunare* or *lapis lunaris*, and gives a process, "de reductione lapidis

ture below the melting point. The once famous *pilulæ lunares* of Boyle consisted of this latter preparation; and Boerhaave, who testified to their purgative efficacy and recommended them in dropsy, expressly forbade the internal use of the pure nitrate of silver.*

Even in this modified form, however, the administration of the silver salt by the mouth had long fallen into disuse, when, in 1794, James Sims directed attention to the employment of the pure nitrate in epilepsy.† It speedily became popular in this disease, but does not appear to have been tried in the fluxes until 1835, when Boudin resorted to it with apparent success, both by the mouth and in enemata, for the diarrhœa of typhoid fever.‡ The report of his observations, published the ensuing year, was speedily followed by an extensive trial of the remedy. It has been recommended in chronic diarrhœas and dysenteries by Macgregor, Copland, Eberle, Trousseau, Graves, Aickin, Waring and others;§ in

---

lunaris in crystallos ad usum medicinæ," by dissolving in pure water and crystallizing. But he expressly mentions that this magisterium may be so skilfully united with pure nitre that the trick cannot be discovered except by the weight of the product; and in his account of the treatment of dropsy—*Ternarius Bezoardicorum*, Cap. XXI, p. 577, *op. cit.*—mentions the use of no silver salt except the *magisterium argenti dejectorium*, which his commentator, ANDREAS TENTZELIUS—*Exegesis chymiatrica*, same Vol., p. 733—explains was made by dissolving nitre in the silver solution and exposing subsequently with certain precautions to heat.

* R. BOYLE—*The usefulness of natural philosophy*, [1663,] Essay V, Ch. 1; I cite Works, Vol. II, London, 1772, p. 115: "And I shall elsewhere (God permitting) teach you a preparation of silver, whereof about three or four grains being made up (with any proper conserve) into a little pill, is wont to make a copious evacuation of serum especially (in bodies, that abound with it) without making the patient almost at all sick, or griping him." In the appendix to this treatise—same Vol., p. 204 *et seq.*—he gives the method of preparing these pills by dissolving equal weights of pure crystals of nitrate of silver and nitrate of potash in separate portions of distilled water, then mixing the solutions and evaporating to dryness, then slowly heating, but with great care lest the mixture should melt, till fumes cease to rise, and finally making the resulting white powder into pills with crumb of bread. He declares that these pills are a specific in dropsy, and useful in the *genus nervosum* and the palsy. He does not seem to have known that the preparation originated with ANGELUS SALA, but writes: "I do not pretend to be the inventor; having divers years since, learned it by discoursing with a very ancient and experienced chymist;" whose name, however, he does not give, because, he says, he is engaged in the "practice of physick," and it might injure him pecuniarily to annex his name to the receipt during his lifetime. BOERHAAVE—Vol. II, p. 296, *op. cit.*, p. 706, *supra*—calls this preparation "the silver pill of Boyle or Angelus Sala," and details the method of preparing it much as it is given by BOYLE. He remarks that the product has an extremely bitter taste, but is less caustic than the nitrate: "And if two grains of it be fine ground with six grains of loaf-sugar, in a glass-mortar, then mixed with ten grains of the crumbs of bread, and formed into nine pills, and these be taken by a grown person upon an empty stomach, drinking after them four or six ounces of hot water sweetned with honey, they will purge gently, and bring away a liquid water, that often deceives the patient, as coming away almost without being perceived. It kills worms, and cures many inveterate ulcerous disorders; it relieves in the dropsy, and purges without griping; but it must not be used too freely, nor in too large a dose, for it always proves corrosive and weakening, especially to the stomach; which inconvenience is remedied by the rob of juniper." In his *Libellus de mat. med.*—I cite the English Transl., London, 1741, p. 172—he recommends these pills as a purge in dropsy. I note that STILLÉ—Vol. I, p. 360, *op. cit.*, p. 711, *supra*—writes as though the pilulæ lunares were simply composed of nitrate of silver, yet W. LEWIS—*Materia Medica*, 2d Ed., London, 1768, pp. 85-86—from whom he borrows the story, tells it correctly. BOERHAAVE, indeed, protested against the internal use of the pure nitrate: "If given internally in this form, it is an immediate corrosive poison; and therefore never to be used in this manner"—*loc. cit.* I may add that in a modified form the compound of SALA and BOYLE still lingers in some of the European pharmacopœias under the designation *argentum nitricum mitigatum*, *argentum nitricum cum kali nitrico*, or *lupis infernalis nitratis*. According to H. HAGER—*Pharmacopœæ recentiores*, Breslau, 1869, p. 23—the German and Russian pharmacopœias direct it to be made of one part of crystallized nitrate of silver and two of nitrate of potash well rubbed together, melted in a porcelain vessel and cast into sticks. BUCHHEIM—S. 257, *op. cit.*, p. 746, *supra*—states that this preparation is chiefly employed as a mild caustic in eye diseases.

† JAMES SIMS—*On the internal use of silver in the epilepsy*, (Read Oct. 20, 1794,) Memoirs of the Med. Society of London, Vol. IV, 1795, p. 379—used a solution of nitrate of silver in water to which he "mostly added a few drops of the nitrous acid, to keep it more certainly suspended." He says: "Of this solution I have given so much at a time as has contained from a twentieth to an eighth part of a grain of the nitrat, beginning with the former quantity, and gradually increasing to the latter; beyond which I do not recollect to have gone"—p. 382.

‡ BOUDIN—*De l'emploi du nitrate d'argent dans le traitement des fièvres typhoïdes*, Gaz. Méd. de Paris, année 1836, p. 812. His first trials were made at the military hospital of Marseilles in the fall of 1835. He gave pills containing each half a grain of the crystallized nitrate with some starch or gum tragacanth; he also used injections containing from $\frac{1}{8}$ to $\frac{1}{4}$ grain to the ounce of distilled water. The latter were to be preferred when the diarrhœa was the dominant symptom, the former when the stomach and upper part of the small intestine were supposed to be chiefly diseased; and both pills and injections were to be employed when the gastro-intestinal mucous membrane was supposed to be inflamed throughout its whole extent. The result was a prompt disappearance of the inflammatory symptoms in the great majority of the cases treated, and no evil effects were observed in any of them.

§ J. J. MACGREGOR—*On the internal use of the nitrate of silver in inflammation of the intestines*, The Lancet, 1840-41, Vol. II, p. 937—commended it in ordinary chronic diarrhœa, but especially in the diarrhœa of phthisis: he gave to one patient pills containing each 1 grain of nitrate of silver and $\frac{1}{4}$ grain of extract of opium with $1\frac{1}{2}$ grains of extract of gentian; "one to be taken after every liquid stool." In two other cases he ordered every three hours a pill containing a grain of nitrate of silver with quarter or half a grain of extract of opium. COPLAND—Vol. I, p. 535, *op. cit.*, p. 682, *supra*—states that he has used the nitrate of silver with advantage in mucous diarrhœa and in chronic fluxes. J. EBERLE—*A Treatise on the Practice of Medicine*, 5th Ed., Philadelphia, 1841, Vol. I, p. 252—says, speaking of the treatment of chronic enteritis: "In some instances, decided advantage has been obtained from the use of nitrate of silver; I have prescribed this article in union with the extract of hyoscyamus with marked benefit. Half a grain of the nitrate, with a grain of the extract, may be given three times daily." TROUSSEAU et PIDOUX—T. I, p. 403, *op. cit.*, p. 716, *supra*—gave to cases of chronic diarrhœa in adults as much as 5 to 10 centigrammes of nitrate of silver daily in pill or solution. TROUSSEAU, in a later work—T. III, p. 112, *op. cit.*, p. 664, *supra*—recommends, in obstinate diarrhœas, pills containing each one centigramme of the nitrate, of which from four to ten should be taken daily for five to ten days. R. J. GRAVES—*Clinical Lectures*, 2d Ed., Dublin, 1848, Vol. II, Lect. 52, p. 228: "Nothing, in my opinion, arrests the colliquative diarrhœa which attends consumption in a more satisfactory manner, than a grain of the nitrate of silver given three or four times a day." T. AICKIN—*On the administration of the nitrate of silver in obstinate forms of diarrhœa and dysentery*, Dublin Med. Press, Vol. XVIII, 1847, p. 193. E. J. WARING—p. 103, *op. cit.*, p. 696, *supra:* "I have employed it extensively in the later stages of acute and in chronic dysentery, in doses never exceeding a grain and a half daily, in combination with Dover's powders; and in almost every instance its administration has been followed by speedy and permanent benefit." Its use in chronic dysentery is mentioned approvingly by AITKEN—Vol. II, p. 659, *op. cit.*, p. 647, *supra;* and among its more recent advocates I may mention G. M. NOBLE—*Treatment of diarrhœa*, Med. and Surg. Reporter, Vol. XXIV, 1871, p. 89—who makes eight pills by mixing 4 grains of silver nitrate with 48 of resin, softened by melting it with lard; he thinks this an excellent remedy in dysentery as well as diarrhœa.

the diarrhœa of infants by Hirsch, Trousseau, Binz and Müller;* in acute dysentery by Hudson, Waring, Meigs and Füner. Trousseau for a time employed in this disease an imitation of the silver pill of Boyle, combining about four-tenths of a grain of the silver salt with an equal quantity of nitre, and repeating the dose till it purged;† but he subsequently was led to abandon this dangerous practice.

At the commencement of our civil war there was considerable diversity of opinion among the medical officers as to the probable usefulness of nitrate of silver in the fluxes. Many were restrained from employing it by the unfavorable opinion of Wood, while others agreed with Stillé, who commended it, in combination with opium, as an excellent remedy in chronic dysentery.‡ It was employed chiefly in chronic cases by a number of surgeons, while others neglected it altogether, or, after trial, abandoned it as useless or injurious.§ These latter observers by no means stand alone in their unfavorable opinion. Both Niemeyer and Heubner have expressed the view that little or no benefit can be expected from the internal use of this salt in dysentery. Morehead gave it in India both to Europeans and natives, but obtained no evidences of its efficacy. Williams saw it administered to a number of cases of chronic dysentery at the German hospital in Philadelphia, but could not recall a single instance in which it produced any decided benefit.‖ Most of the best modern treatises on dysentery are silent with regard to it, or embrace it in the general condemnation they bestow upon almost all mineral astringents in this disease.

Certainly it must be admitted that the testimony adduced in its favor is not of a character to outweigh the grave objections to its use. Not only is it capable, in moderately large doses, of irritating the stomach and bowels,¶ but even small doses, if persisted in for some time, are apt to give rise to chronic silver poisoning, manifested by loss of

* G. HIRSCH—*Bemerkungen über Diarrhœa ablactatorum, Gastramalacie und den Gebrauch des Höllensteins*, Hufeland's Jour. fortgesetzt von E. Osann, Bd. VII, 1840, St. 4, S. 36—gave it in various forms of obstinate diarrhœa, especially that occurring in recently weaned infants. To these he gave every two hours a teaspoonful of a solution containing, in two ounces of sweetened gum water, quarter of a grain of the nitrate—S. 50. To adults he gave every two hours a pill containing $\frac{1}{20}$ to $\frac{1}{12}$ of a grain—S. 52. TROUSSEAU et PIDOUX—*loc. cit.*, last note—gave it to infants in solution, 1 centigramme dissolved in 40 grammes of sweetened water, one-fourth, one-half or even the whole of the mixture to be taken, "suivant l'effet produit." C. BINZ—*Beobachtungen zur innern Klinik*, Bonn, 1864, S. 148—commends nitrate of silver in the dose of $\frac{1}{8}$ to $\frac{1}{4}$ gr. for the chronic diarrhœa of children: "Ich sah niemals nachtheilige Folgen von dieser Dosis;" yet sometimes he found that it vomited (ausgebrochen) even in the dose of $\frac{1}{16}$ gr. MÜLLER (of Riga)—*Der Durchfall der Kinder mit besonderer Berücksichtigung der Therapie*, Journal für Kinderkrankheiten, Bd. L, 1868, S. 331—reports that he had an experience similar to that of BINZ.

† A. HUDSON—*Obs. on the use of nitrate of silver in some affections of the mucous membranes*, The Dublin Jour. of Med. Sci., Vol. XVII, 1840, p. 234—gave it successfully to a case of acute dysentery in grain doses; he also used it internally in gastralgia. WARING—*loc. cit.*, note §, last page. J. F. MEIGS—*Diseases of Children*, 4th Ed., Philadelphia, 1870, p. 403—employed it in the dysentery of children both by the month and rectum; the former mode he found most efficacious. For children two years old he dissolved 1 to 1½ grains in two ounces of sweetened gum water, and gave a teaspoonful every two or three hours. J. FÜNER—*Die Ruhrepidemie in Tobolsk im Jahre* 1863, St. Petersburger Med. Zeitschrift, Bd. VII, 1864, S. 317: "Die innerliche Anwendung dieses Mittels hatte bei weitem mehr Erfolg, als die Anwendung in der Klystierform. Ich verordnete es in Pillenform zu gr. ¼-½, 2 bis 4 Mal im Tage." TROUSSEAU et PIDOUX—*loc. cit.*, note ‖, last page—recommend pills containing, each, 2½ centigrammes of nitrate of silver, the same quantity of nitrate of potash and 5 centigrammes of starch or bread crumb; every half hour one of these is to be taken until they purge: "On donne de demi-heure en demi-heure une pilule semblable jusqu' à ce que le malade commence à être purgé." In his later work—T. III, p. 170, *op. cit.*, p. 664, *supra*—there is no longer any mention of the use of nitrate of silver in acute dysentery except in enemata.

‡ G. B. WOOD—Vol. I, p. 403, *op. cit.*, p. 775, *supra*—though he regarded nitrate of silver as a most effectual remedy in chronic gastritis, declared that he had obtained much less favorable results in chronic enteritis, and expressed the opinion that "it probably seldom enters the small intestines, or at least penetrates far into them, without being decomposed, and thus rendered unable to act on the surface of the bowel in the method above referred to." STILLÉ, in the tract several times referred to—p. 378 *et seq.*, *op. cit.*, p. 650, *supra*—spoke of nitrate of silver and acetate of lead as "the most useful remedies of their class" in chronic dysentery. He advised that they should always be associated with a small proportion of opium.

§ Thus the use of nitrate of silver is favorably spoken of in Section II, *supra*, in the reports of STORROW—p. 43; SCHÜSSLER—p. 44; WRIGHT—p. 62; MUSSEY—p. 82; WALTON—p. 88; and COOPER—p. 93. In the Columbia epidemic of 1868 COUES—p. 64—employed it in acute dysentery. Its employment in chronic cases is also spoken of favorably by BROWER—*Camp diarrhœa*, Transactions of the State Medical Society of Indiana, thirteenth annual session, Indianapolis, 1863, p. 45. I myself spoke favorably of its use in chronic camp diarrhœa on hear-say evidence—p. 258, *op. cit.*, p. 606, *supra:* "Nitrate of silver may be given in pills of $\frac{1}{8}$ to $\frac{1}{4}$ of a grain, every two hours, alone or combined with opium." But I added: "Its use should not be persisted in more than a few weeks, on account of the danger of inducing permanent discoloration of the skin." I do not, however, remember ever to have given it myself. On the other hand, BIGELOW—p 83, *supra*—reported that he used it without benefit; BROWN—p. 81—that it "acted well in some cases, but cannot be relied upon as a rule;" and PENROSE—p. 45—that although it answered in a few cases, in the majority it proved useless or injurious.

‖ NIEMEYER—*loc. cit.*, p. 767, *supra*. HEUBNER—S. 548, *op. cit.*, p. 529, *supra*. MOREHEAD—p. 397, *op. cit.*, p. 657, *supra*. A. WILLIAMS—*A review of the treatment of the principal diseases at the German hospital, Philadelphia*, Med. and Surg. Reporter, Vol. XXXIII, 1875, p. 48; in these cases it was given in pills containing quarter of a grain each of nitrate of silver and opium, and continued "in most cases, for two weeks or more."

¶ BINZ and MÜLLER—cited note *, *supra*—saw quite moderate doses ($\frac{1}{16}$ grain) sometimes excite vomiting in children, and TROUSSEAU—T. III, p. 112, *op. cit.*, p. 664, *supra*—acknowledged that, given in centigramme doses to cases of chronic diarrhœa, it sometimes augmented the flux.

appetite, impaired nutrition and a bluish discoloration of the skin which disfigures the victim: sometimes this latter accident precedes the other symptoms of chronic poisoning; sometimes albuminuria is developed in consequence of silver deposits in the kidneys.* An unfortunate instance of such silver poisoning was observed by Surgeon B. Woodward in the hospital at Tullahoma, Tennessee, during the year 1863. In this case the discoloration appeared after but four weeks' treatment with silver, which, however, did not benefit the chronic flux for which it was administered; and when the patient died, in a miserably emaciated condition, his bowels were found to be extensively ulcerated.† On the whole, I incline to the opinion that it would be prudent to abandon the use of nitrate of silver in the fluxes, except perhaps in the form of enemata, which will be discussed further on.

Butler Lane, who, in 1846, suggested the substitution of the *oxide of silver* instead of the nitrate for internal use, employed it in cases of diarrhœa following typhoid fever and other fluxes;‡ and Da Costa is reported to have given this preparation in the dose of a quarter of a grain four times daily to a case of chronic dysentery with apparent success.§ That this mode of treatment is really advantageous is, however, as far from proven as it is that it is exempt from the dangers of chronic poisoning if long persisted in.

The internal use of the *acetate of lead* also dates back to Paracelsus.‖ Its frigid properties were believed by the iatro-chemists to be useful in fevers and internal inflamma-

* The more important original investigations as to the physiological action of silver are those of L. KRAHMER—*Das Silber als Arzneimittel betrachtet*, Halle, 1845—which I am sorry to say is not in our library; a brief abstract of its contents, by SCHERER, will be found in Canstatt's Jahresbericht for 1845, Bd. IV, S. 245 *et seq.*; B. BALL (under the direction of Charcot)—*Des phénomènes toxiques déterminés par l'injection directe des sels d'argent dans le torrent circulatoire*, Comptes rendus de la Soc. de Biologie, année 1865, p. 4, and Gaz. Méd. de Paris, année XXXVI, 1865, p. 620; BOGOSLOWSKY—*Ueber die Veränderungen, welche unter dem Einflusse des Silbers im Blute und im Bau der Gewebe erzeugt werden*, Virchow's Archiv, Bd. XLVI, 1869, S. 409; A. MOURIER—*Des effets physiologiques et thérapeutiques des préparations d'argent*, Paris Thesis, No. 197, 1871; and C. ROUGET—*Rech. sur l'action physiologiqué de l'absorption des sels d'argent*, Archives de Phys. Normale et Path., T. V, 1873, p. 333. Excellent summaries of the most important facts are given by T. und A. HUSEMANN—*Handb. der Toxicologie*, Berlin, 1862, S. 870 *et seq.*; NOTHNAGEL—S. 302, *op. cit.*, p. 746, *supra*; and BUCHHEIM—S. 251 *et seq.*, *op. cit.*, p. 746, *supra*. With regard to the occurrence of silver deposits in the Malpighian tufts of the kidney and consequent albuminuria, see especially BOGOSLOWSKY—*op. cit.*—and MOURIER—*op. cit.*, p. 17. Chronic silver poisoning has been designated *argyrismus chronicus*, or simply *argyria*. According to KRAHMER—*op. cit.*—the blue discoloration is due to the deposit from the blood of an albuminate of the oxide of silver which is discolored by light; but C. FROMMANN—*Ein Fall von Argyria mit Silberabscheidungen im Darm, Leber, Nieren und Milz*, Virchow's Archiv, Bd. XVII, 1859, S. 135—who found the deposit in various internal organs, also pointed out that this cannot be the sole cause of the reduction; the deposit exists in fine microscopical granules, which consist probably of albuminate of silver modified in some undetermined manner; they were not soluble in ammonia or hyposulphite of soda, but readily dissolved in cyanide of potassium. A similar distribution of the silver pigment in various internal organs as well as the skin has been observed by B. RIEMER—*Ein Fall von Argyria*, Archiv der Heilkunde, Jahrg. XVI, 1875, S. 206, and Jahrg. XVII, 1876, S. 330—who holds that most probably the silver salt is reduced in the alimentary canal, and the granules transported thence to the points at which they are deposited by a mechanical process similar to that which occurs in anthracosis pulmonum and after certain cases of tattooing—Jahrg. XVI. S. 304. BUCHHEIM—S. 255, *op. cit.*—thinks it most probable that the granules are composed of metallic silver, but does not accept RIEMER'S theory of mechanical transport. He points out that in those of the reported cases in which the quantity of silver taken, before the discoloration ensued, is known, it exceeded 30 grammes, and recommends that in the medicinal use of the drug more than 15 grammes altogether should never be given to any individual. According to the HUSEMANNS—*loc. cit.*—EICHMANN has reported two cases in which the silver discoloration was removed by alternate baths of potash and soap. L. P. YANDELL, Jr.—*Cyanosis from nitrate of silver removed by iodide of potassium*, The American Practitioner, June, 1872, p. 329—has reported two, in which the patients being treated for syphilis with large doses of iodide of potassium and mercurial vapor baths, the same happy result was obtained. Most of the cases known have, however, remained incurable.

† See Case 815, p. 249, *supra*.

‡ BUTLER LANE—*On the use of the oxide of silver*, The London Med. Gaz., 1846, Vol. II, p. 640 *et seq.*

§ *Pennsylvania hospital. Medical clinic of* J. M. DA COSTA, Med. and Surg. Reporter, Vol. XXVIII, 1873, p. 10.

‖ His method of preparing it will be found in *De præparationibus*, Lib. I, Tract. 5, T. II, p. 183, *op. cit.*, p. 336, *supra*, where it is commended as an excellent medicine for healing wounds and ulcers. In the jargon of the alchemists, lead was Saturn; tin, Jupiter; iron, Mars; copper, Venus; quicksilver, Mercury; silver, the Moon; gold, the Sun. As each metal had its mystic correspondence with a celestial sphere, so each had its correspondence with a particular part of the human body and with certain morbid conditions. Hence, when we read in PARACELSUS—*De elemento terræ philosophiæ*, Lib. III, Tract. 4, Vol. cited p. 276: "Sol enim melancholiam purgare potest, et Mercurius choleram, et Saturnus febres," &c., we are to understand that gold cleanses from black bile, quicksilver from yellow bile and lead from fevers. Lead cured fevers in virtue of its cold temperament, for Saturn is the son of frigidity—*Lib. Meteorum*, Cap. VII, Vol. cited p. 308: "Saturnus enim ipsius frigiditatis filius est." Hence lead was believed by subsequent iatro-chemists not merely to cure fevers, but to restrain the sexual appetite. Thus OSWALD CROLL—*Basilica Chymica*, p. 391, Ed. cited p. 736, *supra*—wrote: "Sua frigiditate hoc Sal Saturni intra corpus sumptum libidinem Veneream reprimit: Qui in cœlibatu vivere constituerunt, et illo uti volent, consultius facient, si regionem saltem externam admixto aliquo oleo inungant." J. BEGUIN—*Tyrocinium Chymicum*, p. 383, Ed. cited p. 731, *supra*—expressed very similar opinions. SCHRŒDER is cited by MANGETUS—T. II, p. 593, *op. cit.*, p. 736, *supra*—as observing: "Saccharum et magisterium Saturni interne adhibitum chyli et massæ sanguineæ, lymphæque acidum mirifice compescit, fermenta febrilia extinguit et internis inflammationibus viscerum medetur. Externe arcet libidinem priapo inunctum." Yet SCHRŒDER appears doubtful whether, as others believed, the internal use of the lead salts produced this latter effect, for he wrote: "Utrum medicamenta Saturnina totaliter aufferant libidinem et sterilitatem inducant, an secus, disceptatur inter Doctores"—p. 590. But the belief that the external application of lead restrained the sexual appetite is much older than this: I find it in PLINY—*Nat. Hist.*, Lib. XXXIV, Cap. 50, T. IX, p. 4512, Ed. cited p. 771, *supra*: "In medicina per se plumbi usus est cicatrices reprimere: adalligatisque lumborum et renum parti laminis frigidiore natura inhibere impetus Veneris. Visaque in quiete Venerea sponte naturæ erumpentia usque in morbi genus his laminis Calvus orator cohibuisse traditur, viresque corporis studiorum labori custodisse." So, too, in the *Canon* of AVICENNA—Lib. II, Tract. 2, Cap. 12, p. 263, Ed. cited p. 632, *supra*—I read: "Et ligatur lamina super locum renum: et prohibet pollutionem frequentem: et sedat desiderium coitus."

tions;* and its recognized virtues in healing external ulcers early suggested its employment in dysentery. Riverius recommended it for this purpose in ten-grain doses.† Ettmüller, who praised it as a specific in dysentery, employed the same dose, and commended also the famous *tinctura antiphthisica*, a solution of acetate of lead and sulphate of iron, which is described in the Augsburg Pharmacopœia, where it is said that, besides its virtues in curing phthisis and the spitting of blood, it can be usefully employed in the alvine fluxes.‡ Dolæus asserted that it was an admirable remedy in dysentery. Salmon wrote, near the close of the seventeenth century, that acetate of lead had the reputation of being good for diarrhœas, dysenteries and lienteries.§ Indeed, the internal use of lead for these and other diseases became so common, and it was so recklessly administered, that the frequency with which lead colic ensued attracted attention and brought about a reaction.‖

During the eighteenth century the internal use of lead fell into general disrepute. Boerhaave declared that he had not dared to use it, because he had never seen those who did successful, and he knew it to be a deceitful and destructive poison; Geoffroy remarked that it should be reserved for external use only, and Cullen wrote, in 1789, that hardly any practitioner will now think of employing any of the preparations of lead as internal medicines.¶ Nevertheless, even during this period of neglect, the internal use of the acetate of lead always found a few defenders. Hundertmark (1744) insisted that it might be safely and advantageously administered, especially in fevers. White, (1775,) although he yielded to the general clamor so far as to express the opinion that the preparations of lead can never be given internally with propriety, testified that he had known repeated instances in which the continued use of the tinctura Saturnina in phthisis had not only proved innoxious but useful; while Reynolds (1784) boldly advocated both this preparation and the acetate as remedies possessed of singular power in restraining hæmorrhages, declaring that he had frequently employed them with success and safety.**

The essay of Reynolds speedily bore fruit in America. Barton, of Philadelphia, spoke favorably of the use of acetate of lead in uterine and other hæmorrhages, in his lectures on materia medica at the University of Pennsylvania; and Archer, of Maryland, prescribed it in the diarrhœa following acute dysentery during the fall of 1798. He also used it in other obstinate diarrhœas, and his example was followed, in 1799, by his friend, William

---

* See, for example, OSWALD CROLL—*loc. cit.*, last note—who enumerates quartan fevers and internal inflammations among the diseases it cures: see also SCHROEDER, cited last note.

† RIVERIUS—Lib. X, Cap. 6, p. 303, *op. cit.*, p. 680, *supra*. He also commends clysters of rose-water and acetate of lead, (sal Saturni.)

‡ ETTMÜLLER—*De morb. hum. corp. in genere*, Cap. IX, p. 129, *op. cit.*, p. 647, *supra:* "Saccharum seu sal plumb. ad gr. x. est singulare remedium, quod vobis N. B. sit recommendatum. Unde etiam cum hoc sacchar. plumb. præparatur tinctura antiphthisica, quæ est elegans in exulcerationibus internis quibuscunque." This tincture is thus described in the *Pharmacopœia Augustana renovata et aucta*, Augsburg, 1684, p. 307: "Tinctura antiphthisica, ℞. Salis Saturni, Vitrioli Martis artific. ana drachmas duas, Spiritus Vini, Aceti destillati ana unciam semis. Misceantur, et per aliquot dies digerantur, liquor rubicundus filtretur. Præter virtutem antiphthisicam et hæmoptoicam, etiam in alvi fluxibus utiliter adhibetur."

§ DOLÆUS—*Encycl. Med. Dog.*, (1684,) Lib. III, Cap. 5, Opera, Vol. I, p. 241, Ed. cited p. 729, *supra:* "Saccharum Saturni egregium est remedium in dysenteria, ut et alumen." W. SALMON—p 670, *op. cit.*, note *, p. 730, *supra*.

‖ We have on this subject, for example, the testimony of QUINCY—Part II, p. 84, *op. cit.*, p. 734, *supra*—who says, speaking of the tinctura antiphthisica: "But certainly the internal use of all such medicines ought to be rejected, into whose composition the least quantity of sugar of lead enters; whose violent astringency on the kidneys and other glands, has frequently produced irremediable and fatal disorders, even where only very small quantities have been taken." JAMES—*Med. Dict.*, Vol. II, London, 1745, Art. *Colica*—is still more explicit: "And we are assured by practical observations, that medicines, which have lead in their composition, as the tinctura antiphthisica, or the magistery of lead, which quacks frequently use for suppressing a gonorrhœa, leave behind them an invincible costiveness, attended with most tormenting pains."

¶ BOERHAAVE—*Elementa Chemiæ*, Vol. II, p. 289, Transl. cited p. 706, *supra*. GEOFFROY—T. I, (1741,) p. 482, French Transl. cited p. 774, *supra*. CULLEN—Vol. II, p. 28, *op. cit.*, p. 740, *supra*.

** C. F. HUNDERTMARK—*De sacchari saturni usu interno salutari*, Acta Phys. Med. German., Vol. VII, 1744, Append., p. 95. WM. WHITE—*Obs. on the medical virtues of lead*, Med. and Phil. Comm. by a Society in Edinburgh, Vol. III, Part. I, 1775; I cite the 2d Ed., London, 1784, p. 72. The Tinctura Saturnina was a modification of the old tinctura antiphthisica, see note ‡, *supra*. According to QUINCY—*loc. cit.*, note ‖, *supra*—the London Pharmacopœia directed it to be made by digesting, without heat, two ounces each of sugar of lead and green vitriol in two pints of rectified spirit of wine, and filtering through paper. H. R. REYNOLDS—*A letter to Sir George Baker, Bart., on the successful use of the preparations of lead in some hæmorrhages*, (dated Nov. 15, 1784) Medical Transactions, published by the College of Physicians in London, Vol. III, 1785, p. 217. He reports the successful treatment of hæmorrhage from the uterus, hæmoptysis and hæmorrhage from the nose.

Harris, of Mifflin county, Pennsylvania.* In the same year Hildenbrand published an essay in which he lauded its efficacy in phthisis, and related that he had himself taken it with impunity for some time in grain doses repeated several times daily.† This was speedily followed by a pretty general revival of the use of the drug in Germany: it was employed by Amelung and others, chiefly, however, in phthisical cases and hæmorrhages; but in 1807 Hegewisch, of Kiel, declared in one of his clinical aphorisms that there is no remedy at all comparable to it in chronic diarrhœas.‡ In 1808 Thomas Ewell, of Washington, published an account of some cases of intestinal and other hæmorrhages in which he had resorted to it with success, and suggested its trial in dysentery.§

Against this suggestion Fournier and Vaidy made an energetic but futile protest;‖ the acetate of lead speedily came into very general use both in acute dysentery and in the chronic fluxes. Among the European physicians who have lauded it in the former disease may be mentioned Jackson, Burke, Baly, Waring, Tostain and Niemeyer;¶ among American physicians, Harlan, Chapman, T. D. Mitchell, Eberle, Howard, Dickson and G. B. Wood.** Several of these writers have also recommended it in chronic dysentery and in chronic or other diarrhœas, for which it has also been commended by Copland, Graves, Golding Bird and Stillé.†† In acute dysentery its use by the majority of practitioners has been limited to the later stages of the disease, when it has been administered in doses of from one to three grains or more, three to six times daily or oftener, and usually in combination with opium. The same combination has been frequently employed in chronic fluxes.

Long popular in America, the acetate of lead was used in both these groups of cases by a number of the medical officers during the civil war. Several of them report that in their hands it was frequently or generally unsuccessful, and an instance of lead colic from

---

* J. ARCHER—*On the internal use of saccharum saturni (acetate of lead) in diarrhœa*, The Medical Repository, (New York,) Vol. III, 1800, p. 237—gave three times daily a pill containing two or three grains of the acetate. The paper contains a letter from HARRIS, relating his success in treating the diarrhœa of children with the remedy suggested by ARCHER. He gave ½ of a grain every hour or two hours. ARCHER suggested that the remedy would prove useful in the treatment of dysentery, and remarked: "Dr. Barton, you may recollect, in his learned and ingenious lectures on the Materia Medica, mentioned that it had been made use of by several physicians, in hæmorrhagies, with good effect." He also cites REYNOLDS, to whom BARTON also, in a later publication—BARTON'S Edit. of CULLEN'S *Materia Medica*, Philada., 1812, Vol. II, p. 21—has acknowledged his indebtedness. We have the testimony of N. CHAPMAN—Vol. II, p. 505, 4th Ed., *op. cit.*, p. 738, *supra*—that it was through BARTON'S influence that the use of acetate of lead was popularized in Philadelphia.

† HILDENBRAND—*Kleine Beytrüge zur Aetiologie der Lungenschwindsucht; nebst einem Winke zur Heilung dieser Krankheit durch Bleymittel*, Hufeland's Jour., Bd. VIII, St. 4, 1799, S. 3. I append his account of his self-experiment: "Ich habe mich daher entschlossen, an mir selbst einige Versuche mit innerlich genommenen Bleyzucker zu machen. Ich habe—von einem Grane angefangen—drey, vier, fünf und mehrere des Tags durch lange Zeit, ohne die geringsten unangenehmen Folgen—ausser einer stark vermehrten Esslust—genommen"—S. 24.

‡ AMELUNG—*Einige Bemerk. und Beob. über die innerliche Anwendung des Bleizuckers vorzüglich bei Geschwüren der Lungen*, same Jour., Bd. XXII, St. 1, 1805, S. 1: see also KARL F. BURDACH—*System der Arzneimittellehre*, Leipsic, 1807, Bd. I, S. 328 *et seq.* HEGEWISCH—*Klinische Aphorismen, Zweite Dekade*, Horn's Archiv, Bd. VI, Heft 2, 1807, S. 215: "In den hartnäckigsten chronischen Bauchflüssen—aber ich spreche im Superlativ—ist kein andres Heilmittel, als Bley." That he meant the acetate, is clear from the comments of RICHTER—Bd. IV, S. 125, *op. cit.*, p. 777, *supra*.

§ THOMAS EWELL, (of Washington, D. C.)—*Account of the internal exhibition of the acetate of lead in several diseases*, The Medical Repository, (New York,) Vol. XI, 1808, p. 249. His conclusions were made known in Europe by a brief paragraph in the Med. and Phys. Jour., Vol. XXII, 1809, p. 350, and appear to have attracted much attention.

‖ FOURNIER et VAIDY—p. 384, *op. cit.*, p. 362, *supra*: "Cette proposition, qui décèle une ignorance complette des propriétés délétères de ce poison, est une vision si absurde, qu' elle ne nous paraît pas mériter une réfutation."

¶ R. JACKSON—pp. 441 and 455, *op. cit.*, p. 770, *supra*. ULIC BURKE—*On the good effects of a mixture of acetate of lead and tincture of opium, in the dysentery which occurred in Dublin in 1825; with a short description of that epidemic*, The Edinburgh Med. and Surg. Jour., Vol. XXVI, 1826, p. 56. BALY—p. 537, *op. cit.*, p. 535, *supra*. WARING—*Therapeutics*, p. 496, Ed. cited p. 696, *supra*. II, S. 756, *op. cit.*, p. 645, *supra*.

** R. HARLAN—*Cases illustrative of the good effects of sugar of lead in dysentery*, The American Medical Recorder, (Philadelphia,) Vol. V, 1822, p. 655. I note that the Editors, JOHN EBERLE and H. W. DUCACHET, protested against his views, remarking: "We have given it in four or five cases, and in one of these its effects were unequivocally injurious;" but EBERLE outlived his objection—see *loc. cit.*, *infra*. CHAPMAN—Vol. II, p. 507, 4th Ed., *op. cit.*, p. 738, *supra*. T. D. MITCHELL, (of Frankford, Penna.,)—*Practical hints on the use of the acetate of lead, in dysentery, cholera infantum, &c.*, The North American Med. and Surg. Jour., (Philadelphia,) Vol. I, 1826, p. 70. JOHN EBERLE—Vol. I, p. 244, *op. cit.*, p. 778, *supra;* also 1st Ed., 1830, Vol. I, p. 216. C. C. HOWARD—*Remarks on dysentery*, Southern Med. and Surg. Jour., Vol. XI, 1855, p. 78. S. H. DICKSON—*Elements of Medicine*, Philadelphia, 1835, p. 532—advised it to be combined with ipecacuanha and opium. G. B. WOOD—Vol. I, p. 722, *op. cit.*, p. 671, *supra*. He, however, carefully limited it to the later stages of the disease, "after sufficient depletion and a thorough evacuation of the bowels," to hæmorrhagic cases and to chronic dysentery.

†† COPLAND—Vol. I, p. 535, *op. cit.*, p. 682, *supra*—recommended it especially in the diarrhœa of phthisis; R. J. GRAVES—Vol. I, p. 132, *op. cit.*, p. 778, *supra*—in the diarrhœa accompanied with tympanites, observed in typhoid fever; GOLDING BIRD—see Report of *Meeting of Med. Society of London, Feb.* 9, 1846, The Lancet, 1846, Vol. I, p. 277—in diarrhœa following fever; A. STILLÉ—*loc. cit.*, p. 779, *supra*—in chronic dysentery.

its rash employment was reported by Medical Inspector Wm. H. Mussey;* but as a rule it does not appear to have been pushed to this extreme. It has continued since the war to enjoy the confidence of certain American practitioners, and we occasionally hear its innocence maintained in extravagant language.†

Nevertheless, from time to time voices of warning have been heard. The danger of the production of lead colic from excessive doses has been insisted upon by cautious physicians from the very first. Bampfield accused it of doing harm by producing constipation and subsequent increase of the morbid secretions;‡ Morehead declared that the trials he made with it failed to inspire him with confidence, and regarded its use in chronic dysentery as generally inexpedient, because in such cases it is important to improve the general state of the constitution, a result which is not to be looked for from a salt of lead;§ Savignac and Barrallier exclude it from the treatment of dysentery along with all other mineral astringents except the salts of iron; Maclean and Heubner have both formally expressed their want of confidence in its usefulness.‖

It may aid in deciding between these conflicting views if we recall what is known of the physiological action of the preparations of lead. That any of the soluble salts of this metal in excessive doses may irritate or inflame the gastro-intestinal mucous membrane is well established;¶ but it is probable that the ordinary medicinal doses of the acetate are quite innocent in this respect, and that so far as the danger of giving rise to local injurious effects is concerned it is safer than any of the mineral astringents hitherto discussed. Indeed, a consideration of its operation upon external inflammations would suggest that in moderate doses its influence upon the inflamed intestine may be beneficial.

Not so, however, with the constitutional effects of the drug. The facts with regard to chronic lead poisoning are too well known to be overlooked.** The quantity capable of

* See, for example, in Section II, *supra*, the reports of SCHÜSSLER—p. 44; BELLOWS—p. 70; HOUGH—p. 75; WAINWRIGHT—p. 78; BRETZ and SCHEETZ—p. 80; PECK and GRIMES—p. 86; WALTON—p. 88; and GAGE—p. 93. I myself—p. 229, *op. cit.*, p. 606, *supra*—spoke favorably, in 1863, of the use of the drug in the advanced stages of dysentery; but I added, "care should be taken not to push the remedy too far, or symptoms of lead poisoning will be induced. After from fifty grains to a drachm have been administered, the remedy should always be discontinued." See also J. T. CALHOUN—*Rough notes of an Army Surgeon's experience, during the great rebellion, No.* 19, Med. and Surg. Reporter, Vol. X, 1863, p. 68—who recommends that the treatment of "camp diarrhœa" should be begun with a cathartic, followed by acetate of lead, sulphate of copper or nitrate of silver combined with opium. His favorite combination, however, was persulphate of iron with quinine and opium. H. N. FISHER—*loc. cit.*, p. 697, *supra*—reports that a combination, known as "Gouley's Pill," consisting of one grain each of opium and ipecacuanha and two of acetate of lead, was employed at the Eckington hospital with good results in some cases, but that it failed in others: this was the combination preferred by DICKSON—*loc. cit.*, note **, last page. For more adverse views, see the testimony of HOLSTON—p. 66, *supra;* W. W. BROWN—p. 81; and the report of MUSSEY—p. 79.

† Thus J. L. LUDLOW—*Medical clinic. Chronic diarrhœa*, Med. and Surg. Reporter, Vol. XIV, 1866, p. 307—is reported to have said at the Philadelphia hospital: "Many patients object to the continued use of lead for fear of producing lead poisoning; but in this house we have used bushels of it, and never saw any evil results." Among the recent American advocates of the use of this salt in the fluxes is H. C. WOOD—p. 38, *op. cit.*, p. 675, *supra:* "Its chief use at present is in *diarrhœa*. On account of its sedative properties, when the purging is attended with inflammation, it is the most serviceable of all the astringents; and, owing to the promptness of its action, it is also very valuable in cases with profuse serous discharges. In *dysentery* it is very useful whenever the discharges have become copious. The dose is from two to five grains, always in pill, repeated *pro re nata*."

‡ BAMPFIELD—p. 198, *op. cit.*, p. 682, *supra*.

§ MOREHEAD—p. 306, *op. cit.*, p. 657, *supra*. More than this, after condemning the use of the salt in the earlier stages of acute dysentery—a practice he affirms to have been too common in India—he writes: "It is difficult to understand how a system of treatment which evinces both ignorance of the therapeutic action of acetate of lead and of the pathology of acute dysentery can have originated."

‖ SAVIGNAC and BARRALLIER—see the passages cited in note *, p. 773, *supra;* MACLEAN—*loc. cit.*, note **, p. 775, *supra;* and HEUBNER—*loc. cit.*, note ‖, p. 779, *supra*.

¶ Thus CLARUS—S. 791, *op. cit.*, p. 766, *supra*—wrote: "Sehr grosse Gaben löslicher Bleipräparate dem Magen zugeführt, bewirken gleich anderen Metallsalzen, sei es durch Reizung der berührten Nerven oder durch unmittelbare chemische Verbindung mit dem Eiweiss der Berührungsflächen, Anätzung, Gastroenteritis mit heftigem Schmerz, Erbrechen, Auftreibung des Leibes, zuweilen Diarrhöe, Dyspnöe und Erscheinungen von Collapsus." Compare NOTHNAGEL—S. 269, *op. cit.*, p. 746, *supra*, and BUCHHEIM—S. 239, *op. cit.*, p. 746, *supra:* see also FALCK—S. 159, *op. cit.*, next note.

** I shall not attempt to sketch the literature of this interesting and important subject. The reader who desires an introduction to it may begin with the elaborate work of L. TANQUEREL DES PLANCHES—*Traité des Maladies de Plomb ou Saturnines*, Paris, 1839—a copy of which has been received by our library since note ‖, p. 413, *supra*, was stereotyped. Among the numerous more recent works may be mentioned those of C. PH. FALCK—*Die klinisch wichtigen Intoxicationen*, in Virchow's Handb. der spec. Path. u. Ther., Bd. II, Abth. 1, Erlangen, 1855, S. 158 *et seq.*—which contains a good bibliography up to the date of publication; A. GUSSEROW—*Untersuchungen über Bleivergiftung*, Virchow's Archiv, Bd. XXI, 1861, S. 443; E. LANCEREAUX—*Note relative a un cas de paralysie saturnine*, &c., Mémoires de la Soc. de Biologie, T. IV, 1862, p. 75 *et seq.;* A. EULENBURG—*Differentes Verhalten der Muskeln gegen intermittirende und continuirliche Ströme bei Paralysis saturnina*, Deutsches Archiv für klin. Med., Bd. III, 1867, S. 506; E. HITZIG—*Studien über Bleivergiftung*, Berlin, 1868; E. HEUBEL—*Pathogenese und Symptome der chronischen Bleivergiftung*, Berlin, 1871. Excellent summaries of the facts have been given by the HUSEMANNS—S. 914 *et seq., op. cit.*, p. 780, *supra;* B. NAUNYN—*Vergiftungen durch schwere Metalle und ihre Salze*, Ziemssen's Handb., Bd. XV, 1876, S. 255; and BUCHHEIM—*loc. cit.*, note ¶, *supra*. The principal phenomena are anæmia and

producing this effect undoubtedly varies considerably with different individuals and under different circumstances; but there are cases recorded by trustworthy observers in which broken doses, administered until two drachms, a drachm, half a drachm, or even less were taken, have proved sufficient to produce unmistakable and serious toxic symptoms.* Moreover, the extent of the possible mischief resulting from inducing the constitutional impression of the lead salt in individuals already anæmic or cachectic, to the degree so often observed in the advanced stages of acute dysentery or in the chronic fluxes, is not to be measured by the frequency of the development of the more obvious symptoms of lead poisoning, such as colic or paralysis.† Before these symptoms occur the effects of this metal are manifested by the production of digestive disturbances and of a peculiar anæmia which is quite characteristic. A few years since Malassez‡ applied his method of enumeration to this form of anæmia and found that it could readily be recognized by actual count; indeed, in extreme cases the number of red blood corpuscles was diminished one-half. This poorness in globules persisted after the disappearance of the acute toxic accidents which undoubtedly it often precedes.

It appears impossible to believe that the induction even of minor degrees of the lead anæmia can be beneficial to the anæmic victims of acute or chronic alvine fluxes; and nothing but conclusive evidence that the acetate of lead is more beneficial to the local process than any of the more harmless remedies at our disposal would justify its selection for this purpose. This evidence we do not possess: although, as has been shown, a number of respectable practitioners have lauded its efficacy in these diseases, no trustworthy com-

nutritive disturbances, (cachexia saturnina;) a peculiar pale-yellowish or grayish color of the skin, (gilvor saturninus;) a blue discoloration of the gums, (gingiva saturnina,) sometimes also of other parts of the oral mucous membrane, (livor oris saturninus;) a brownish discoloration of the teeth, (dentes saturninæ;) a characteristic taste in the mouth, (gustus saturninus;) a peculiar odor of the body, (fœtor saturninus;) digestive disturbances, (dyspepsia saturnina;) emaciation and debility, (macies et infirmitas saturnina.) Sooner or later during the progress of the case serious local disorders supervene, especially lead colic, (colica saturnina;) pains in the joints, (arthralgia saturnina;) paralysis, (paralysis saturnina;) and various other disorders of the brain and nervous system, (such as tremor saturninus, anæsthesia saturnina, epilepsia saturnina, encephalopathia saturnina, &c.) It is worthy of note that a catarrhal condition of the mucous membrane of the alimentary canal is one of the most frequent accidents observed after death in fatal cases, and that minute examination has demonstrated a deposit of lead, probably in the form of an albuminate, in almost all the tissues and organs of the body. The relation in which the latter fact stands to the toxic symptoms, especially in view of the remittent or intermittent character of some of them, is not so clearly understood as could be wished. As in the case of chronic silver poisoning, chronic kidney disease and albuminuria sometimes supervene. One of the reporters in Section II, SCHÜSSLER—p. 44, *supra*—preferred the acetate of lead to tannin, "from its tendency to increase the secretion of the kidneys, which the tannin rather diminishes." This idea is altogether erroneous. Ordinary medicinal doses of acetate of lead usually exercise no influence on the activity of the secretion of urine in persons whose kidneys are healthy; but we have the testimony of FR. MOSLER und W. METTENHEIMER—*Zur Wirkung der Adstringentien auf die Harnorgane*, Archiv der Heilkunde, Jahrg. IV, 1863, S. 522 *et seq.*—that large doses diminish the urinary secretion, and that this diminution is accompanied by a diminution in the solid constituents, especially of the urea, the chlorides and the sulphates.

* TANQUEREL DES PLANCHES—Vol. I, p. 64 *et seq.*, *op. cit.*, last note—has collected the testimony of a number of writers with regard to the production of lead colic by the internal administration of the acetate of lead, and expressed the opinion that this accident is more common than is generally supposed—p. 70. In one of these cases, reported by TISSOT—*Obs. sur la colique de plomb*, Œuvres, Lausanne, 1788, T. V, p. 164—the patient took five grains of the acetate three times a day for six days, in all 90 grains, with the effect of developing, a few days after, severe lead colic and paralysis of the upper extremities. WM. LAIDLAW—*Remarks on the internal exhibition of the acetate of lead, chiefly with the view of determining to what extent it may be safely administered in the cure of diseases, especially in uterine hæmorrhages; with cases*, The London Med. Repository and Review, Vol. VI, 1828, p. 33 *et seq.*—took himself, while in good health, three times daily a pill containing 3½ grains of acetate of lead; 40 grains were thus taken "without any other perceptible inconvenience having been produced than a metallic taste, and perhaps some tenderness of the gums and constipation;" but ten grains more, taken at once, produced pain in the stomach, nausea and a sense of weakness at the knees. These symptoms were removed by a dose of salts. A month later he resumed the experiment, and took similar doses for eight days, in all 70 grains, when the symptoms became so severe that, "consulting with Dr. Henry Davies, it was agreed, that the severity of the symptoms rendered it advisable to put a termination to the process"—p. 293. He concluded from these experiments that medicinal doses should not be pushed beyond seventy grains in all. He mentions, indeed, a case—p. 294—in which 75 grains were administered without serious symptoms, but admits that this cannot always be done: "Some patients I have found with whom it could not be carried beyond twenty grains, without inducing vertigo, nausea, and in others, even vomiting." TROUSSEAU et PIDOUX—*Traité de Thér. et Mat. Méd.*, T. I, p. 139, Ed. cited p. 716, *supra*—relate that LÉRIDON, of Buzançais, administered to a patient six grains of acetate of lead daily for three days, with the result of developing violent lead colic. L. S. JOYNES—*Case of colica pictonum, from the medical employment of acetate of lead—with remarks*, The Stethoscope, (Virginia,) Vol. I, 1851, p. 664—gave pills of acetate of lead and opium to a man aged 25, suffering with chronic diarrhœa: "The entire quantity taken was 30 grains, in the course of about four days." The diarrhœa was checked without any immediate ill consequence; but a fortnight later violent lead colic set in and continued for eight days. REYNOLDS and HARLEY—*Case of lead colic arising from the medicinal employment of the acetate of lead*, The Lancet, 1863, Vol. II, p. 507—report an instance in which a laboring man, suffering with phthisis and diarrhœa, received two grains of acetate of lead and ½ grain of powdered opium thrice daily until he had taken 108 grains: a blue line on the gums and unmistakable lead colic resulted.

† With regard to the occurrence of paralysis from the effects of the internal administration of acetate of lead in dysentery, see p. 413, *supra*.

‡ L. MALASSEZ—*Rech. sur l'anémie saturnine*, Mémoires de la Soc. de Biologie, 1873, p. 125 *et seq.*—assumes 4,500,000 red globules per cubic millimetre as the normal standard for the healthy man. This he saw fall in extreme cases to 2,600,000, 2,400,000 and even 2,200,000. He states that the globules are increased in size from 7–7.5 thousandths of a millimetre in a healthy individual to 9–9.5 in lead poisoning; but shows by calculation that, owing to the diminished number, both the total volume and total surface of all the globules in a given volume of blood are really diminished.

parative observations exhibiting its superiority have been recorded; and the testimony that condemns it as inefficient or injurious is, to say no more, quite as trustworthy as that which appears to favor it. If, nevertheless, in special cases, particularly in those complicated with hæmorrhage from the bowels, the practitioner ventures to administer this poisonous salt, the total quantity given should be rigidly limited. It is a good rule not to exceed a drachm in any case; but the symptoms will not unfrequently indicate to the careful observer the desirability of suspending the drug before this point is reached.

Drying remedies.—Of the various substances of this kind approved by Galen,* the medicinal earths have fallen into almost complete oblivion. Savignac, as late as 1863, speaks of *Armenian bole* as occasionally employed in France, but it has completely disappeared from English and American practice.† The same author praises the *subcarbonate of iron* in the dose of one to two grammes in chronic dysentery;‡ and certainly this preparation is less objectionable than the more astringent salts of iron; yet on the whole it is probably advisable that chalybeates should only be employed in the fluxes for their specific action on the blood, and in no greater dose than is sufficient to effect that end.

Most of the great variety of *calcareous preparations* employed by Galen§ have also disappeared from modern practice. These preparations may be divided into two groups, the first consisting chiefly of the phosphate, the second the carbonate of lime. The calcined hartshorn and other calcined horns and bones of the Greek physicians are represented in modern English and American practice only by the precipitated *phosphate of lime*,‖ and this is rarely employed in the treatment of the fluxes. Savignac, however, used it in chronic diarrhœa and dysentery, and employed also calcined and pulverized bones under the same circumstances as the carbonate of lime, and without preference for either.¶ Of the preparations consisting essentially of the *carbonate of lime*, prepared chalk and prepared oyster-shell are still retained in the United States Pharmacopœia, as well as the precipitated carbonate, which fully represents their medicinal properties.**

The credulity of the middle ages endowed some of the substances belonging to this group with diaphoretic virtues; but this belief died out during the last century.†† The supposition that they act as absorbents, their dry, porous substance imbibing the foul juices of the diseased intestine, the acrimony of which is thus mitigated, has survived longer, but appears to have no sure foundation. Van Swieten held that the irritating acrimony in the bowels was acid in some cases, alkaline in others; in the first instance cretaceous preparations were beneficial, in the latter injurious.‡‡ Pringle, in his earlier practice, sometimes

* See p. 762, *supra*.

† SAVIGNAC—p. 404, *op. cit.*, p. 620, *supra*—remarks that Armenian bole is essentially a silicate of alumina mingled with oxide of iron, and approves its administration in the dose of 10 to 20 grammes. I note that it is still officinal in the French *Codex* of 1866, p. 100, and that GUBLER, in his *Commentaries*—p. 457, *op. cit.*, p. 777, *supra*—as late as 1874 approved its employment in chronic dysentery, mucous diarrhœa, &c., with the additional remark that "les Bols de Blois ou de Paris ont une composition semblable et servent aux mêmes usages."

‡ SAVIGNAC—p. 409, *op. cit.*—remarks: "Le sous-carbonate de fer, ou safran de mars apéritif, est l'un de nos meilleurs ferrugineux corroborants, et, de plus, il tonifie localement l'intestin et tend à réprimer les flux diarrhéiques." He especially favors the composition of 10 grammes of bismuth with 1 of the subcarbonate of iron and .05 of opium, declaring that this is one of the formulæ he has employed most frequently and with the greatest success in chronic dysentery.

§ See p. 762, *supra*.

‖ The *calcii phosphas præcipitata* of the U. S. Pharmacopœia of 1870; the *calcis phosphas* of the British Pharmacopœia of 1867.

¶ SAVIGNAC—p. 408, *op. cit.* French pharmacy is very conservative. In the *Codex* of 1866 we still find deers' horns, *cornes de cerf*—p. 49—and burnt bones, *os calcinés*—p. 111—as well as the prepared phosphate of lime, *phosphate de chaux*—p. 215.

** Under the titles *creta præparata*, *testa præparata* and *calcii carbonas præcipitata*. The French *Codex* of 1866 also retains coral, *corail rouge*—p. 49—and the so-called crabs' eyes, *yeux d'écrevisse*—p. 51.

†† This belief was still firmly held in the seventeenth century. Thus, for example, SYLVIUS—Lib. II, Cap. 11, p. 107, *op. cit.*, p. 730, *supra*—in enumerating the sudorific remedies, remarks: "Idem dicendum de oculis cancri, coraliis, margaritis, conchis, et similibus, quæ acido peccante usurpata non semel sudorem movent." In the 3d edition of DALE'S *Pharmacologia*, London, 1737, p. 365, we still read of oyster-shells: "Testæ vim habent exsiccandi, sudorem movendi, abstergendi, &c."

‡‡ VAN SWIETEN—§ 722, Vol. II, p. 389, *op. cit.*, p. 663, *supra*.

prescribed a chalk julep in dysentery, but found it to disagree so much oftener than other astringents that he ceased to use it. Subsequently he brought it again into use, but only in diarrhœa or those cases of dysentery in which there was marked gastric acidity.*

Of late years the employment of cretaceous preparations in the fluxes has been limited by many prudent practitioners to those cases in which evidences of acidity in the primæ viæ are recognized, and in these they are prescribed chiefly with a view to their antacid effect.† That they are frequently useful in such cases is probably true; nor is it improbable that in the later stages of intestinal catarrhs they may serve to diminish the excessive secretion of the intestinal mucous membrane, and to some extent therefore deserve their old reputation as drying remedies. But their action is, after all, not very energetic, and probably few practitioners will share the great confidence with which Savignac speaks of their effects in the treatment of chronic fluxes.‡ As ordinarily administered, they are combined with opium and vegetable astringents to the extent of quite masking their feebler action; and the rarity with which they are prescribed alone may serve to indicate the slight confidence reposed in their restraining virtues by the average practitioner.§

Equally safe, but far more efficacious than any of these venerable remedies, is the *subnitrate of bismuth.* Unknown to the ancients,‖ this metal had been isolated, and was already designated by its present name by the German miners before the middle of the fifteenth century. It is mentioned in the writings of Basil Valentine and Paracelsus,¶ and Agricola, who described it about the year 1529, has left us a detailed account of the method by which it was separated.** The metallurgists of the first half of the sixteenth century for the most part regarded lead, bismuth, tin and antimony as constituting a nearly

* PRINGLE—p. 288, 1st Ed., *op. cit.*, p. 693, *supra:* "At first I used the chalk julep, but being soon sensible of its bad effects, both in the beginning and low state of the disease, I left it off; tho' I could not then so well account for its disagreeing oftner with the sick than other astringents: but having since found by experiments, that both the chalk and the testacea are of a septic nature, it seems reasonable to reject them here." In the experiments referred to—Appendix, Paper 3, Exp. 23, same Vol., p. 320—he exposed ox gall and water, or flesh and water, to gentle heat, with and without prepared crabs' eyes, prepared chalk, &c., and found that with the addition of these substances putrefaction took place more speedily than without them. In his 7th edition he speaks of giving the chalk julep "when the patient complained of a heart-burn, and of everything turning sour on his stomach"—p. 272—and "for correcting that strong acid so incident to relaxed stomachs"—p. 281; also in diarrhœa—p. 207, note.

† See STILLÉ—Vol. I, p. 346, *op. cit.*, p. 711, *supra;* NOTHNAGEL—S. 198, *op. cit.*, p. 746, *supra;* H. C. WOOD—p. 569, *op. cit.*, p. 675, *supra.*

‡ SAVIGNAC—p. 408, *op. cit.*, p. 620, *supra:* "J'accorde une grande confiance aux préparations calciques insolubles dans le traitement des dysentéries et des diarrhées chroniques."

§ The *mistura cretæ* of the U. S. Pharmacopœia consists simply of prepared chalk rubbed up with gum Arabic and water, with the addition of some glycerine and cinnamon. As actually administered, some laudanum or paregoric, with the tincture of kino or catechu, is almost always added.

‖ We have the testimony of OLAUS WORM—*loc. cit.*, next page—that it has been supposed to have been one of the varieties of plumbum described by PLINY: see *Nat. Hist.*, Lib. XXXIV, Cap. 47–50, Vol. IX, p. 4507 *et seq.* According to that author there are two genera of lead, the black and the white, (nigrum atque candidum.) The former is our lead; the latter, called cassiteron by the Greeks, (κασσίτερος by HOMER,) is our tin. Of ordinary lead (plumbum nigrum) there were three varieties, known as Ovetanum, Caprariense, Oleastrense, but these titles appear to have served merely to indicate the places in which favorite mines existed: see Editor's note—*loc. cit.* AVICENNA—Lib. II, Tract. 2, Cap. 12, p. 262, Ed. cited p. 632, *supra*—mentions two varieties of plumbum nigrum, Alaunoch and Alahabar. He attributes to them indifferently cold and moist properties, and regarded them as useful in healing wounds, ulcers, &c.: see note ‖, p 780, *supra.* That one of these varieties was really antimony, as is suggested by FALLOPPIUS—*loc. cit.*, next page—is a conjecture unsupported by anything in the account of the Arabian writer.

¶ In the *Handwörterbuch der reinen und angewandten Chemie* of H. v. FEHLING—Bd. IX, Brunswiek, 1864, S. 710—I read: "Basilius Valentinus im 15 Jahrhundert spricht zuerst von Wismuth als einem Metall." Our library possesses none of the works of BASIL VALENTINE except that cited on p. 689, *supra*, so that I have been unable to verify this statement, which, however, I do not doubt. PARACELSUS threw around the subject the halo of his wonderful imagination. For him—*Philosophiæ de generationibus elementorum*, Lib. IV, Tract. 3, T. II, p. 280 *et seq.*, Ed. cited p. 336, *supra*—the metals were all compounds of different properties of salt, sulphur and mercury, and in nature coexisted with marcasitæ and cachimiæ. Both of these were superfluities, consisting of the same elementary substances that form the metals, but ejected by the Archeus of the metals during their generation, and the resulting compounds varied in properties according as salt, sulphur or mercury predominated. Zinc and bismuth—Cap. 10, p. 282—were a like sort of superfluity, capable of being extracted from marcasitæ. They were generated from the residuum after the separation of other metals; they were themselves both metals and not metals; zinc was the spurious offspring of copper, and bismuth of tin. Elsewhere he classes marcasitæ as a variety of cachimiæ—*De mineralibus*, p. 350, same Vol.—for we read: "Nomina cachimiarum. Marcasitæ, pyrites, antimenia, cobalta, talka, auripigmenta, sulphura, arsenicalia. Tot mihi nota sunt." And we learn in both places that there are two kinds of marcasitæ, the yellow and the white. For more on the subject of marcasitæ, bismuth and zinc, see *Archidox.*, Lib. II et III, same Vol., p. 8 *et seq.* I may add that in this edition zinc is always written *zinetum* or *zinetus*, but I do not doubt that the English translator of the *Archidoxes*, &c., London, 1661, p. 24, correctly renders it *zinck.*

** T. THOMSON—*System of Chemistry*, 3d Ed., Edinburgh, 1807, Vol. I, p. 292—says that AGRICOLA described it in his treatise called *Bermannus*, written at least as early as 1529; and L. GMELIN—*Handbook of Chemistry*, Vol. IV, English Transl., London, 1850, p. 427—says that it was "recognized as a distinct metal by Agricola in 1529." The treatise of G. AGRICOLA—*Bermannus, sive, de re metallica dialogus*—was printed at Basel in 1530; I have not been able to see it, but in the Italian version of his *De re metallica Libri XII*, Basel, 1563, Lib. IX, p. 375, there is an account of the method of separating this metal, which he names plumbum cinereum, (piombo cinericcio in the version I cite.) Like the other processes in the work, this is illustrated by a rude but striking engraving.

allied group, as being in fact so many genera of plumbum. This view was expounded by Falloppius, Cardanus (1550) and Aldrovandus,* but I do not understand them to have in any way confounded bismuth with the other metals. The question was a purely speculative one, relating merely to the classification of bodies which resembled each other in certain particulars, and Falloppius expressly affirmed that bismuth differed in its nature from both tin and lead. But whatever interpretation may be put upon the language of these writers, it is at least certain that Olaus Worm (1655) described bismuth as a peculiar metal, quite distinct from lead or the others of the group, so that it is an error to credit Stahl with having been the first to take this view.†

The chemists of the sixteenth and seventeenth centuries learned to make a magistery of bismuth by precipitation, and flowers of bismuth by sublimation;‡ and some of them ventured to give these preparations, especially the flowers, internally, supposing them to

---

* GABRIEL FALLOPPIUS, (died, 1562,) in Cap. 22 of his treatise *De metallis seu fossilibus*—published posthumously, Venice, 1564, T. I, p. 383, edition cited p. 706, *supra*—treated at some length on the nature of bismuth. He cites the passage of PLINY, referred to in note ‖, last page, and explains that the plumbum nigrum of the ancients is common lead, and was so called because it blackened the hands; their plumbum album is our tin, (stannum,) but their stannum was either an alloy of silver and lead, obtained on the first flowing from the furnace from argentiferous lead ore, or it was an alloy artificially prepared and of various composition. PLINY makes three species of plumbum nigrum, but rather on account of the places of origin than any difference in nature. AVICENNA makes two species, but I [FALLOPPIUS] know only one, and suspect AVICENNA intended antimony by his second: (Verum non nisi unum genus nigri plumbi novi ego; et Avicenna per alterum genus intelligat de stibio, nescio quid dicam.) To these two the moderns have added a third kind, which in certain places in Germany is called *bisve*, and is named by others plumbum cinereum vel cinerulentum, on account of its lustre. But this differs in its nature from the nature of lead and tin, (ejus tamen natura differt a natura plumbi nigri et plumbi albi.) it is friable and can be reduced to a powder not only by a pestle and mortar but by the fingers. Melted with tin it makes it harder; hence it is called "marchasita librariorum, vel impressorum," because those who engrave letters on statues and vases mix it with the tin to make it retain the characters longer. Moreover, this mixture is used by the Venetians who manufacture tin vessels, which are made more shining as well as harder, although they do not wear so well as those made of tin alone. HIERONYMUS CARDANUS—*De subtilitate*, (1550,) Lib. VI; I cite Opera, Lyons, 1663, T. III, p. 457—stated briefly that there are four species of lead: p. nigrum, the common lead; p. album, commonly called tin, (stannum:) bismuth, only recently discovered, a sort of intermediate between lead and tin, (bismuthum hucusque incognitum, quasi medium inter nigrum et album,) and even in our own age not generally known, since it is found only in the mountains of Bohemia; the fourth species is antimony, (stibium.) ULYSSES ALDROVANDUS, (died, 1605,) in his posthumous work—*Museum Metallicum*, Bologna, 1648, Lib. I, Cap. 7, pp. 160–61—apparently borrows most of his account of this subject from the two writers just cited. After discussing p. nigrum, p. album and stibium, he remarks: "Nuperi authores, et potissimum Cardanus speciebus enumeratis quartam, nempe plumbum cinereum addunt, in Germania vocatum bismuthum, quod inter nigrum, et album medium quodammodo locum occupat; juxta vulgatum carmen. *Candidius nigro, sed plumbo nigrius albo.*" He refers to the title marchasita librariorum mentioned by FALLOPPIUS, and remarks that he has learned from the metallurgists that antimony is the substance used to give hardness to type-metal.

† OLAUS WORM (died, 1654)—*Museum Wormianum*, published by his son, Amsterdam, 1655, Lib. I, Sect. 3, Cap. 8, p. 125—made a separate group of bismuth, antimony and mercury, which he calls peculiar metals, or metals improperly so called, (De sui generis, seu improprie dictis metallis;) because although they have a great affinity to the true metals, they differ in being neither ductile or malleable, but instead are frangible, friable or fluid. He calls it plumbum cinereum, and says it owes this name to AGRICOLA. The metallurgists call it bismuthum; CÆSALPINUS called it marcasita argentea, (I suppose in his work, *De Metallicis*, Rome, 1596, which I have been unable to see;) the Germans call it *Wismut, Mythin* and *Conterfeit*. Some have supposed it to be the plumbum argentarium of PLINY, others think it was unknown to the ancients. As to its nature he pointedly remarked: "Potius sui generis metallum esse puto, quam ut ad plumbum referatur. Differt namque ab utroque plumbo colore et duritie." He adds a description of the ore from which it is obtained, which, he says, occurs in the silver mines of England and Saxony, (Anglia et Misnia.) It is often added as an alloy to tin to give it hardness and lustre, as well as to make it melt more readily. Vessels are thus produced which emulate silver in appearance. So far as he knew it had no use in medicine, except that BEGUIN relates how to prepare a cosmetic *(fucus)* from it for whitening the skin. G. E. STAHL—*Obs. chymico-physico-medicarum curiosarum, mensis sextus, December*, Frankfort, 1697, Cap. 2, p. 321, *De plumbo antimonii, pauca*—earnestly enough declares that those metallurgists, metallicolæ, who include lead, tin, bismuth, (or marcasita fusilis,) the regulus of antimony and still more lately zinc, under the single rubric "plumbum," are rather empirics than physico-chemists. This paper is republished in his *Opusculum Chymico-Physico-Medicum*, Halle, 1715, p. 489. In the same volume is his *Diss. posterior metallurgiæ pyrotechnicæ*, in which—Cap. 3, pp. 790–91—he classes bismuth, zinc and antimony as metalliform minerals. As our library does not contain the rest of the chemical works of STAHL, I know not what more he may have written on this subject, but as he was not born until five years after the posthumous work of OLAUS WORM was published, it is absurd to attribute to him the credit of having first recognized that bismuth should not be confounded with tin and lead, as has been done by STILLÉ—Vol. I, p. 184, *op. cit.*, p. 711, *supra*—who writes, on whose authority he does not tell: "Bismuth was confounded by the ancients with tin and lead, and was first distinguished from them by Stahl." I must add that I do not at all suppose that I have found references to all the earlier accounts of bismuth, and especially I regret that I have not been able to consult the essay of J. H. POTT—*Observationes de Wismutho*, in his *Obs. et Animad. Chym. Collectio*, T. I, Berlin, 1739—which is said by THOMSON—*loc. cit.*, note **, last page—to embrace "every thing respecting it contained in the writings of the alchymists." Nor have I been able to see a copy of the work of G. REILINGS—*Collectanea curiosa de bismutho*, Leipsic, 1718—which is also said to be rich in alchemical details.

‡ Already PARACELSUS in his *Archidoxes*, Lib. VI, p. 22—Vol. cited note ‖, p. 780, *supra*—writes concerning the preparation of magisteries from the various kinds of marcasitæ, specifying, among others, the bismuthic (bisemutica) marcasita. And here I must say a word with regard to the meaning of the term marcasite, (spelled variously marcasita, marcassita, marchastia, &c.) It appears to have been originally bestowed by the German miners on various composite, not very rich ores, but not indiscriminately on all, and to have been used with a somewhat different signification by different writers, and even by the same writer at different times. Compare the definitions of MANGETUS—T. II, p. 210, *op. cit.*, p. 733, *supra*—and JAMES—*Med. Dict.*, Vol. II, London, 1745—word *Marcasita*. The marcasita pallida was an ore that yielded zinc, and marcasita argentea yielded bismuth. Later writers sometimes used the word marcasite as an equivalent for bismuth: *e. g.*, SCHREDER, cited by DALE (1693)—p. 31, Ed. cited p. 729, *supra*—which was not the original usage. According to DALE—*loc. cit.*—bismuth was also sometimes called tin-glass. I will not take space to detail the various processes applied to bismuth, or the ore from which it was derived, by the chemists of the sixteenth and seventeenth centuries. In the work of MANGETUS—T. I, p. 418—a formula is given from ROLFINCIUS for the formation of a magistery of bismuth by the precipitation of a solution of the metal in nitric acid with salt of tartar, and one—same Vol., p. 932—for the preparation of flores bismuthi by subliming together calcined marcasite and sal armoniac. The method of preparing the magistery given by QUINCY—Part II, p. 111, *op. cit.*, p. 734, *supra*—is to precipitate a solution of bismuth in nitric acid with a solution of common salt in water; he directs the flowers to be prepared by subliming powdered bismuth with nitre.

possess diaphoretic virtues similar to those attributed to mineral bezoar.* The magistery of bismuth, our subnitrate, found more extensive use as a cosmetic, and the fashionable women of the seventeenth century enhanced the whiteness of their charms with this adhesive powder as those of our own age still do.† But the leading therapeutists of that century and the next denounced the internal use of these preparations in such unmeasured terms that they were never generally employed in this way, and had become quite obsolete,‡ when Odier of Geneva, in 1786, drew attention to the beneficial effects of the internal administration of the magistery of bismuth in certain forms of gastralgia, and thus brought about its introduction into modern therapeutics.§

It is unnecessary here to trace the history of its employment in gastric affections: references to a few of the more important papers are subjoined in a foot note.‖ It appears to have been first employed in the treatment of the fluxes by Leo, of Warsaw, who used it in 1831, during the prevalence of Asiatic cholera, in the dose of two or three grains every two or three hours, and claimed for it greater virtues in the cure of this disease than subsequent experience has shown it to possess.¶ In 1833 Trousseau published a paper** in

* I suppose the internal use of the bismuth preparations is unquestionably as old as PARACELSUS—*De præparationibus, Lib. I*, Vol. II, p. 75, *op. cit.*, p. 336, *supra*—who lauds both the marcasita aurea and m. argentea as possessed of special virtues in restraining hæmorrhages. They should be mixed with pitch and colophon and reduced to a calx, which was to be given internally to those who spat blood. QUINCY—*loc. cit.*—remarks of the flowers of bismuth: "But if the nitre and the arsenical salts are washed away by frequent solutions in warm water, it will not only continue to be a good cosmetic, but may also with safety be given internally; and by some is reckoned a good diaphoretic. Yet as the materia medica is large enough in its supply for that intention; there is no occasion to torture a poison to make a medicine of it. Its dose and virtue, in the manner directed, are the same as of the bezoar mineral"—*i. e.*, butter of antimony dropped into three times its weight of nitric acid, dried and calcined—Part II, p. 110, same Vol. GEOFFROY—T. I, p. 417, *op. cit.*, p. 774, *supra*—states that some prepare flowers of bismuth, which they assert to be diaphoretic, but that most persons dread the internal use of this mineral on account of the arsenical parts contained in it. POTT—*op. cit.*, note †, last page—must have been one of those who experimented with its internal use, for MÉRAT and DE LENS—*Dict. Universel de Mat. Méd.*, T. I, Paris, 1829, p. 605—state that he reported a case in which vomiting, colic, anxiety and vertigo followed its ingestion.

† Thus BEGUIN—*Tyrocinium Chymicum*, Lib. II, Cap. 11, p. 271, Ed. cited p. 731, *supra*—describes, under the head of calcinatio marchastiæ argenti, a process for making magistery of bismuth by precipitation, and adds, "usus ejus est ad cutis vitia." SCHRŒDER is cited by DALE—*loc. cit.*—as saying, "usus rarissimus est, et non nisi externus;" to which DALE adds, "nonnulli ex eo fucum elaborant ad cutim dealbandam." QUINCY—*loc. cit.*—says of the flowers of bismuth: "These are very white, and used as an excellent fucus, mixed with pomatum, or rose-water: but they must not be too busy with it, who try it upon their complexions; for the saline part of the arsenic may do mischief many ways."

‡ Besides SCHRŒDER, QUINCY and GEOFFROY, I may cite ALSTON—Vol. I, p. 332, *op. cit.*, p. 772, *supra:* "Bismuth is commonly reckoned an arsenical substance, and as such safe neither inwardly nor outwardly, being worse than lead. But perhaps without sufficient reason; it seeming to partake more of the nature of antimony, than of either of these, or of tin. However it is very little used, if it be not, as a cosmetic, reduced to flores, or a magisterium." LEWIS—p. 142, *op. cit.*, p. 778, *supra*—writes that the flowers and magistery of this metal "have been recommended externally against gleeting sores, and internally as diaphoretics similar to the milder antimonial medicines. In the first intention, they appear to be greatly inferiour to some of the saturnine preparations: in the latter, it is not certain what their real effects are, or even whether they are safe. At present, they are employed only as a fucus, nor is this use of them entirely innocent; for they gradually impair the natural complexion, and, as the college of Strasburg observes, occasion a thickness and defedation of the skin." CULLEN, in his *Materia Medica—op. cit.*, p. 740, *supra*—did not deign to mention bismuth.

§ L. ODIER—*Sur les effets du magistère de bismuth, donné intérieurement comme antispasmodique*, Jour. de Méd. Chir. Pharm., &c., T. LXVIII, 1786, p. 49—gave it at first in fractions of a grain, but soon growing bolder gave 2–3 grains or more at a dose. He writes that perhaps he may give larger doses after more experience, but as yet has never gone beyond 12 grains four times a day. While lauding its beneficial effects, he admitted that in a small number of cases the patients on first taking it experienced vomiting, diarrhœa or constipation, vertigo, &c.

‖ BAUME—*Obs. sur les vertus du magistère de bismuth sur trois sujets attaqués d'une douleur chronique de l'estomac*, same Jour., T. LXXIV, 1788, p. 69. B. CARMINATI—*Hygiene, Therapeutice et Materia Medica*, Vol. II, Pars I, Pavia, 1792, p. 439—where he cites a former work on the subject, "*Opuscula Therapeutica*, Pavia, 1788, Vol. I, Opus 2," which I have not seen. A. MARCET—*Obs. on the medical use of the white oxyd of bismuth*, Memoirs of the Medical Society of London, Vol. VI, 1805, p. 155. This physician learned of the remedy from ODIER himself, and though he calls it white oxide, meant, as he explains, the magistery of bismuth, "prepared by dissolving a quantity of very pure bismuth in nitric acid, and precipitating it by water, or by a solution of potash." S. A. BARDSLEY—*Medical Reports*, London, 1807, p. 218, *On the medical effects of the white oxyd of bismuth.* S. W. MOORE, New York—*An Inaug. Diss. on the medical virtues of the white oxide of bismuth*, 1810; I cite from a review in The Eclectic Repertory, (Philadelphia,) Vol. I, 1811, p. 234. Both this writer and BARDSLEY use the term white oxide in the same sense that MARCET did.

¶ L. LEO—*Ideen u. Erfahr. über die Natur und Behandl. der asiat. Brechruhr, mit besonderer Beziehung auf die Anwendung des Wismuths gegen dieselbe*, Warsaw, 1832. I have not been able to see this work, but learn from a letter of LEO, dated June 11, 1831, which HUFELAND published in his Journal—Bd. LXXII, 1831, St. 5, S. 138—that he gave the magistery of bismuth, in the dose mentioned in the text, with a little sugar. But from the very first his sanguine views failed to be sustained by the experience of others. LEWESTAN—same Jour., Bd. LXXIII, 1831, St. 2, S. 116—reported the same year that of 24 cholera patients treated in this manner at Dantzig, 18 died. TROUSSEAU—T. IV, p. 263, *op. cit.*, next note—found it inefficacious except in the stage of choleraic diarrhœa; in the acute period of algid cholera he regarded it as, to say the least, useless. MONNERET—T. XLVII, 1854, p. 268 *et seq.*, *op. cit.*, next page—who so stoutly advocated the use of bismuth in very large doses in the fluxes, and who found it exceedingly useful in cholerine and other forms of epidemic diarrhœa, honestly confessed, "que le sous-nitrate de bismuth, si utile dans les diarrhées et les cholérines actuellement régnantes, échoue complétement dans le choléra bien caractérisé."

** A. TROUSSEAU—*De l'emploi du sous-nitrate de bismuth dans le traitement de la diarrhée*, Bull. Gén. de Thér., T. IV, 1833, p. 261—found it useful in acute diarrhœa; he gave it twice daily, 12 to 18 grains, in pill or powder. In acute gastro-enteritis with colic and vomiting, as well as diarrhœa, and in sporadic or epidemic dysentery, it should not be given till the violence of the acute symptoms is subdued by other medication; but its usefulness is greatest in chronic diarrhœa, in which he gave 18 to 36 grains daily with immense advantage, (avantages immenses.) He was not very successful in the diarrhœa of phthisis, but more so in colliquative diarrhœa proceeding from other causes. See also TROUSSEAU et PIDOUX—T. II, p. 752, *op. cit.*, p. 716, *supra*, and TROUSSEAU—T. III, p. 113, *op. cit.*, p. 664, *supra*.

which he commended its efficacy in the dose of twelve to thirty-six grains daily for acute and chronic diarrhœa. But it was especially Monneret, whose enthusiastic praise of the action of this preparation in the fluxes brought it into extensive use in their treatment, and whose boldness in administering it served to demonstrate that it is quite innoxious. In an essay, published in 1850, he lauded its effects in the acute and chronic diarrhœas of children and adults, and even in acute dysentery. In the diarrhœas of adults he gave it in the dose of ten grammes daily for the first few days, and then, if the disease continued, gradually increased the dose to fifty or even to seventy grammes; in acute dysentery he gave as much as sixty to seventy grammes a day with decided benefit. In subsequent papers he reported continued success, and ridiculed the ignorance of those who imagined the drug to be possessed of poisonous properties.*

After the publication of the observations of Trousseau and Monneret the use of bismuth in the fluxes rapidly became popular, especially in France. It was given with advantage in the acute and chronic diarrhœas of both children and adults,† in the diarrhœa of typhoid fever and of phthisis.‡ Some have even gone so far as to rely upon it as the most important therapeutic agent in acute dysentery. This was done by Monneret in sporadic cases; by Pellieux in an epidemic that occurred in the vicinity of Beaugency in 1852; by Maillot the following year in the dysentery of Algeria; and in the dysentery of Guadeloupe during 1860 and 1861 by Brassac, who also employed it with success in chronic fluxes.§

During our civil war the subnitrate of bismuth was employed to some extent, especially in diarrhœa and chronic dysentery; but it was by no means so generally tried as would have been desirable. Acting Assistant Surgeon John B. Trask used it successfully at Camp Downey, California, in the fall of 1861, in the treatment of an epidemic outbreak of diarrhœa: in many of these cases he gave it in combination with calomel. Encouraged by his success he employed it uncombined during August and September, 1862, at Finley hospital, Washington, in the diarrhœas, chiefly chronic, which prevailed among the wounded brought from the Army of the Potomac, as well as in other cases. The quantity administered varied from forty-five to eighty grains daily, usually given in a single dose. An account of these observations, published in April, 1863, drew attention to the subject, and

* MONNERET—*Du sous-nitrate de bismuth à hautes doses*, Bull. Gén. de Thér., T. XXXVIII, 1850, p. 433; also, *De l'emploi du sous-azotate de bismuth à haute dose, dans le traitement de diverses maladies*, same Jour., T. XLVII, 1854, pp. 113, 209 and 265—in which he remarks: "Les toxicologues et les auteurs de traités de thérapeutique, qui écrivent sans observer, ont construit un roman qui ne laisse pas encore que d'en imposer aux véritables praticiens, trop modestes, cependant, pour oser douter de ce qui est écrit dans les livres qu'on appelle plaisamment classiques"—p. 113. See also *Du mode d'administration du sous-nitrate de bismuth et de son emploi thérapeutique*—same Jour., T. LXXI, 1866, p. 481—where he explains more fully his views with regard to the mode in which the remedy acts.

† In the diarrhœa of children it has been employed by TROUSSEAU and MONNERET; HUBER—*Einige Bemerkungen über die Behandlung der Kinderdurchfälle*, Deutsches Archiv für klin. Med., Bd. VI, 1869, S. 107; J. SENSEMAN—*The uses of subnitrate of bismuth*, Med. and Surg. Reporter, Vol. XXIV, 1871, p. 131, and many others. In the diarrhœa of adults by SCHINA, of Turin—see an article in the Bull. Gén. de Thér., T. XLV, 1853, p. 274, *Un mot sur l'emploi du sous-nitrate de bismuth dans la diarrhée;* N. GUÉNEAU DE MUSSY—*Leçons cliniques sur la diarrhée chronique*, Gaz. des Hôpitaux, 1872, p. 114—who, however, does not wish to give more than 6 to 12 grammes a day to adults; and by many others.

‡ In the diarrhœa of typhoid fever by BRIQUET and ARAN—see an article in the Bull. Gén. de Thér., T. XL, 1851, p. 317, *Emploi du sous-nitrate de bismuth à haute dose pour arrêter les diarrhées qui succèdent à la fièvre typhoïde.* In the diarrhœa of phthisis, especially by MONNERET, and THEOPHILUS THOMPSON—*On the utility of trisnitrate of bismuth in the diarrhœa accompanying phthisis*, Med.-Chirurg. Trans., Vol. XXXI, 1848, p. 305. TROUSSEAU was not so successful with it in such diarrhœas—see note **, last page.

§ MONNERET—*loc. cit.*, note *, *supra*. PELLIEUX—see an article in Bull. Gén. de Thér., T. XLII, 1852, p. 428, *Nouveaux faits à l'appui de l'emploi du sous-nitrate de bismuth à haute dose dans le traitement de la dyssenterie.* He is said to have given 8 to 30 grammes a day to adults; 4 to 13 to children: the results surpassed his hopes. MAILLOT—see an article in the Bull. Gén. de Thér., T. LXXV, 1868, p. 560, *De l'emploi du sous-nitrate de bismuth à haute dose dans le traitement des affections dysentériques en Algérie*—introduced this practice in 1853. It was attended with such success that the annual consumption increased until in 1868 the supply forwarded from Marseilles for the military hospitals in Algeria was 460 kilogrammes. I may add that I find by the *Statistique Médicale de l'armée pendant l'année* 1868, Paris, 1870, p. 61, that the strength of the army in Algeria that year was 55,773 present, and the hospital admissions for diarrhœa numbered 1,805, with 30 deaths; for dysentery, 1,625, with 72 deaths—p. 201—which does not include the more trifling cases treated in quarters. BRASSAC—*Du sous-nitrate de bismuth*, Archives de Méd. Navale, T. V, 1866, p. 161 *et seq.*—treated 14 cases of acute dysentery with subnitrate of bismuth in large doses in 1860; all recovered; four of these cases had been treated with ipecacuanha and calomel before entering hospital. Of 10 chronic cases, 7 were cured and 3 improved—p. 286. His subsequent experience with the remedy continued to be favorable, both in acute and chronic dysentery and in diarrhœa, the only drawback being the difficulty of getting a sufficient supply to enable him to use it after the method of MONNERET.

led to the trial of the remedy by others, especially in the hospitals of Washington and Alexandria.* Some of the medical officers who used it obtained excellent results, but this was by no means universally the case.† That it was not more generally successful was due in part to the circumstance that it was very often given in insufficient quantity, or combined with other drugs which impaired its efficiency, but doubtless chiefly because too much was expected of it, and because it was given indiscriminately without regard to the character of the intestinal lesion or the constitutional condition of the patients.

In endeavoring to form an opinion of the place of this remedy in the treatment of the fluxes, its mode of operation must be taken into consideration. When properly prepared, and entirely free from arsenic or other injurious foreign admixture, it is an almost wholly insoluble powder, and the only benefit to be expected from it is its local action upon the mucous membranes with which it is brought in contact.‡ Headland insists that this local action is purely mechanical, while Fonssagrives invokes for it also a local sedative influence. If the prompt manner in which it acts when dusted upon raw or inflamed surfaces of skin or mucous membrane, as in intertrigo, coryza or vulvitis, be compared with the more tardy and less efficient action of other insoluble powders in similar conditions, we shall be inclined to accept the latter suggestion.§ The investigations of Bergeret and Mayençon seem to prove that it is so acted upon in the alimentary canal that minute quantities are absorbed; but we are entirely without evidence to show that this circumstance is either beneficial or injurious.‖ Nearly the whole of any dose administered is evacuated by the stools, a part

* JOHN B. TRASK—*Report on the treatment of acute and chronic diarrhœa, with sub-nitrate of bismuth, at Camp Downey, Cal., and Finley Hospital, Washington, D. C.*, San Francisco, 1863. This pamphlet is in the form of a report to Surgeon R. H. COOLIDGE, U. S. A., Medical Director of the Department of California, and is dated April, 1863. From the account given—p. 7 *et seq.*—the epidemic at Camp Downey appears to have been one of those outbreaks of catarrhal diarrhœa which were so common among the newly levied volunteers—see p. 286, *supra*. The strength of the command was 500 men, the number of cases of diarrhœa 94. Of these 20 were treated with bismuth alone, and 58 with bismuth combined with calomel. The bismuth was given in the dose of 10 to 50 grains; the calomel, 3 to 10 grains; all the patients recovered. At Finley hospital the number of cases treated was 270, of whom 182 were wounded men who had diarrhœa besides their wounds. In all these cases the disease was "promptly and radically" arrested.

† See the report of Surgeon T. RUSH SPENCER—p. 50, *supra;* also the reports of SCHÜSSLER—p. 44; SCHELL—p. 70; BRETZ—p. 80; and TUTTLE—p. 90. WOOSTER—p. 100—reports that he obtained good results with a combination of bismuth and blue mass, neither proving adequate alone. WELCH—p. 96—reports the successful use of the subcarbonate. See also the reports of my own experience, and what I had learned verbally from others—p. 258, *op. cit.*, p. 606, *supra*—and p. 126 of *Circular No.* 6, cited p. 571, *supra*. On the other hand, KEMPSTER—*op. cit.*, p. 493, *supra*—reported that the subnitrate of bismuth in two-scruple doses failed so often in the chronic diarrhœas he observed during the war that he abandoned its use.

‡ This was the view of MONNERET—see T. XLVII, 1854, p. 118 *et seq.*, and T. LXXI, 1866, p. 481, *op. cit.*, note *, last page.

§ F. W. HEADLAND—*On the Action of Medicines*, Amer. reprint of 4th London Ed., Philadelphia, 1868, p. 105—writes: "The nitrate of bismuth"—of course he means our subnitrate—"is a very insoluble salt. It passes down along the mucous surface of the intestine, and is not absorbed. Being insoluble, its action is quite confined to the mucous surface. It may be given safely in very large doses (as 5j, or more,) and it is probable that its anæsthetic action is simply mechanical in nature, and depends upon its affording a soothing sheath to the irritable and painful surface of the stomach. So that it is only by covering this, and not at all by an influence on the stomach nerves, that it operates as a local anæsthetic. In the bowel also it sheathes the surface, and absorbs irritating fluids. It is not a true astringent, and counteracts certain forms of diarrhœa in something the same manner as chalk." GUBLER—p. 680, *op. cit.*, p. 777, *supra*—writes: "Mais, à part les effets antispasmodiques qu'on est porté à lui attribuer, on ne lui connaît aucune action manifeste lorsqu'il est parvenu dans la circulation. En qualité de poudre sèche il s'imbibe des liquides. C'est donc tout à la fois un antacide et un absorbant mécanique." FONSSAGRIVES—Art. *Bismuth*, Dict. Encyclop. des Sciences Méd., T. IX, 1868, p. 527: "Un certain nombre de médecins ne voient dans le sous-nitrate de bismuth qu'un moyen mécanique, une sorte de poudre-mastic jouant, par rapport aux muqueuses, un rôle préservateur, ou mitigeant par l'interposition d'une poudre inerte, l'âcreté des liquides gastro-intestinaux. Je crois que, dans beaucoup de cas, il faut faire intervenir cette action, mais pour sa part seulement, et qu'il y a lieu d'invoquer une action *sédative* locale, antispasmodique si l'on veut, exercée par ce médicament sur les filets nerveux avec lesquels il est en contact et de laquelle résulte une diminution dans la sensibilité de la muqueuse gastro-intestinale et dans la motricité des plans musculaires qui la doublent." He further suggests—p. 532—that in diarrhœa it proves useful by absorbing the sulphuretted hydrogen that may be present in the alimentary canal; a circumstance to which W. F. MCNUTT—*Some of the uses of bismuth*, California Med. Gazette, Vol. I, 1868-69, p. 129—believes its efficacy is almost entirely due. This latter view appears to me to be an exaggerated one. To the efficacy of the local action of subnitrate of bismuth used externally in the conditions mentioned in the text and similar ones, I can bear unequivocal testimony from much personal observation.

‖ BERGERET et MAYENÇON—*Recherche du bismuth dans les tissus et dans les humeurs*, Jour. de l'Anat. et de la Phys., 9me année, 1873, p. 243—used a test-paper charged with sulphocyanide of potassium: this gives a yellow stain on contact with a soluble salt of bismuth. With this test they were always able to recognize bismuth in the urine of patients a few hours after it had been taken internally. In rabbits to whom they had administered it, they were able to recognize it in all the tissues and organs of the body, even when eight days elapsed after it was given before the animals were killed. In the cadaver of a man who had taken one gramme of the subnitrate a few days before death, they recognized it in the liver and kidneys, but failed to find it in the cadaver of a woman who had taken two grammes of it twelve days before death. They also found it in the fluid of an ovarian cyst in a patient who had taken two grammes a short time before. They conclude that the subnitrate of bismuth is promptly absorbed and infiltrates all the tissues, that it is slowly eliminated, and that it seems to augment the plasticity of the blood. This latter statement appears to rest upon a single observation: The blood of a rabbit which had taken bismuth coagulated very firmly! I may add that ORFILA—T. II. p. 13, *op. cit.*, p. 699, *supra*—had previously detected bismuth in the urine, liver, spleen, &c., of dogs poisoned by the soluble protonitrate of bismuth. His paper—*Nouvelles recherches sur plusieurs poisons tirés du règne minéral*, Annales d'Hygiène Publique, T. XXVIII, 1842, p. 219—speaks of the detection of bismuth in animals poisoned by it, but does not detail experiments, and I presume the statement is based simply on his former work with the soluble nitrate.

of it at least in the form of sulphuret, which blackens the discharges. No trustworthy observations can be adduced to show that the internal use of pure subnitrate of bismuth ever influences the circulation, the nervous system or the secretions, except indirectly in consequence of its local action upon the alimentary mucous membrane.

The evidence brought forward during the present century to prove that it may occasionally exert a poisonous influence does not sustain criticism. This evidence consists of experiments upon animals, alleged cases of poisoning, and reports of certain disagreeable effects said to be occasionally observed after medicinal doses. The experiments upon animals most generally cited are those of Orfila and Mayer. The first used the soluble nitrate, the poisonous properties of which may be conceded, in some of his experiments; in others he complicated the result by the fatal operation of ligature of the œsophagus. In the instances he reports, in which the subnitrate introduced into the stomach appeared to act as a corrosive poison, as in the similar observations of Mayer, it is exceedingly probable that the drug was contaminated with arsenic, as has been proved to be the case in certain recent instances of human poisoning; at least no steps were taken to exclude this source of error.*

As for the alleged cases of poisoning which figure in the works on toxicology, I find on investigation that the one attributed to Sobernheim is merely a garbled version of that reported by Kerner; and that in this the reporter, as long ago as 1835, publicly confessed that he had been misled by an ignorant chemist† who examined the remains of the medicine which produced the symptoms, and declared it to be subnitrate of bismuth, whereas it

* ORFILA—T. II, p. 10 *et seq.*, *op. cit.*, last note. MAYER—*Ueber das Wismuth*, &c., Hufeland's Jour., Bd. LXXIII, St. 4, 1831, S. 65. For the fatal effects of ligature of the œsophagus, see the account of the discussion on the subject in the French Academy of Medicine by M. SÉE—*Acad. de Med.: ligature de l'œsophage*, &c., Gaz. Hebdomadaire, T. III, 1856, p. 669 *et seq.*, and *Ligature de l'œsophage au point de vue toxicologique*, same Vol., p. 642 *et seq.* The experiments reported in these articles show not merely that death is produced by this operation, but the inflammatory lesions are observed in the stomach, &c., on dissection, although no poison has been taken.

† JUSTINUS KERNER—*Geschichte einer tödtlichen Vergiftung durch basisches salpetersaures Wismuth*, Neue Jahrb. der teutschen Med. und Chirurg., (Heidelberg klin. Annalen.) Bd. XIV, Heft 3, 1829, S. 348. A drunkard, suffering with severe gastric trouble, (sodbrennen,) took about two drachms of what was supposed to be a mixture of magnesia and cream of tartar. Symptoms of corrosive poisoning were developed, and death ensued after nine days' suffering. On dissection, patches of inflammation and gangrene were found in the fauces and throughout the intestinal canal. A quantity of the powder used remaining on hand, a part of it was submitted to chemical analysis and reported to be subnitrate of bismuth, (das basische salpetersaure Wismuth.) This story is repeated by ORFILA—T. II, p. 14, *op. cit.*, *supra;* FONSSAGRIVES—T. IX, p. 538, *op. cit.*, last page; in England by CHRISTISON—*On Poisons*, 1st Amer. from 4th Edinburgh Ed., Philadelphia, 1845, p. 384—who remarks: "The following is the only case with which I am acquainted of poisoning with the preparations of bismuth in the human subject." From CHRISTISON it was copied by PEREIRA—T. I, p. 673, Ed. cited p. 746, *supra*, and I regret to find it also in the work of STILLÉ—Vol. I, p. 186, *op. cit.*, p. 711, *supra*. All these writers have been ignorant of the fact that a few years after his original publication, KERNER—*Eine tödtliche Vergiftung durch weisses Quecksilberpräcipitat. Zur Berichtigung eines Irrthums*, Heidelberg, Med. Annalen, Bd. I, Heft 3, 1835, S. 479—with commendable frankness related that, although at the first he had been satisfied with the accuracy of the chemist who had decided the powder to be bismuth, he took the remains of it, with the written report of the chemist, and submitted them to a control-investigation at the medical college. Circumstances long delayed the examination there, to which no particular importance appears to have been attached. At length a complete and exact analysis was made, which revealed the almost inexcusable error that had been committed, (den allerdings fast unverzeihlichen Irrthum der ersteren,) and demonstrated beyond doubt that the metallic portion of the powder consisted of the white precipitate of mercury, *(Mercur. præcip. albus.)* The writer, therefore, begs leave to correct his former error, and recapitulates his original narrative to make the correction more emphatic. This article is abstracted, under the title *Mercurius præcipitatus albus. Vergiftung*, in J. Frank's Magazin, Bd. III, 1850–51, S. 262; and the matter is correctly stated in the work of the HUSEMANNS—S. 861, *op. cit.*, p. 780, *supra;* but since the correction does not appear to have reached England and America, I have thought proper to draw special attention to it. J. F. SOBERNHEIM—*Handbuch der praktischen Arzneimittellehre*, 4te Aufl., Berlin, 1855, S. 268—after relating KERNER'S case as one of bismuth poisoning, without any mention of the subsequent correction of this error, relates another in which, after taking two drachms of the subnitrate, fatal symptoms of corrosive poisoning were developed. This second case has been accepted as an independent one by STILLÉ—*loc. cit.;* TAYLOR—*On Poisons*, 3d Ed., London, 1875, p. 487; and others. I believe it, however, to be a mere duplication of KERNER'S case, and for the following reasons: The two narratives are wonderfully alike. In both the poisonous dose was two drachms, and the essential features of the symptoms and post-mortem appearances agree, although, as SOBERNHEIM tells the story, KERNER'S case died on the 15th day; the second case on the 9th, and KERNER'S case was not salivated while the second case was. To this I can only say that the difference of date is a blunder which shows that SOBERNHEIM did not consult the original account of KERNER, who expressly states that his patient took the drug on the 14th of May and died on the 23d, that is, in nine days after taking the poison. As for the salivation, it is true that in his second paper KERNER expressly states that his patient was not salivated: "Eine Spur von Speichelfluss war nie vorhanden"—S. 481, *op. cit.*, *supra;* but when he wrote this he had evidently forgotten that in his original narrative he had stated that the patient, when first seen, complained of a disagreeable taste in the mouth, (beschwerte sich immer über einen widrigen Geschmack im Munde.)—S. 350—which on the 16th is spoken of as metallic, (der widrige metallische Geschmach im Munde war H. sehr lästig;) and that in his account of the symptoms, on the 18th, he had stated that much thick saliva of a brown color and metallic taste was secreted: "Es wurde viel dicker Speichel, der braun anssah und metallisch schmeckte, abgesondert"—S. 353. So that CHRISTISON—*loc. cit.*, *supra*—who borrowed the case from the very fair abstract in Férussac's Bull. des Sci. Méd., T. XX, 1830, p. 188, *Hist. d'un empoisonnement mortel par le sous-nitrate de bismuth; rapportée par le Dr. J. Kerner*, was not inaccurate when he wrote: "On the fourth day swelling and tension of the belly were added to the preexisting symptoms, on the fifth day salivation, on the sixth delirium, on the seventh swelling of the tongue and enormous enlargement of the belly, and on the ninth he expired." It follows from this analysis that SOBERNHEIM'S second case is, like his first, a garbled version of KERNER'S, clipped from some second-hand source. He does not state that he witnessed it himself, and gives no authority for it. Sound criticism cannot do otherwise than reject it as a duplication which indicates little discernment on the part of the toxicologists who have accredited it.

proved on subsequent examination to be really the white precipitate of mercury. It is discreditable to medical literature that these cases continue to be cited as examples of poisoning by bismuth. There remain three cases in which symptoms resembling those of arsenical poisoning followed the use of this remedy, but in which the patients recovered. In that reported by Traill the drug was not chemically analyzed, but in those related by Fullerton and Hebert this precaution was taken, and a sufficient quantity of arsenic found to account for the symptoms.* It must, therefore, be conceded that no trustworthy evidence exists to show that this preparation, when pure, is ever poisonous in any dose.

To the abundant testimony already published with regard to the impunity with which large doses of the pure drug may be given, I may add the results of my own personal experience. I have often taken myself, and administered to others, one- and two-drachm doses, repeated thrice, four times or oftener daily, for several days without the slightest unpleasant consequences, and without any perceptible effect except the arrest of the diarrhœa for which it was taken. As for the minor disagreeable effects said to follow occasionally its medicinal use, such as headache, a sense of gastric vacuity, nausea or even vomiting, they are for the most part phenomena, accidentally coexisting, for which the remedy is not responsible; but may sometimes have resulted, especially in the case of the older observations, from arsenical or other contamination.†

The scorbutic and cachectic symptoms, described by Lussana as having occurred in certain cases of chronic tubercular and other fluxes, variously treated for a considerable period with large doses, I suppose, from a study of his narrative, to have been phenomena of the disease rather than of the drug. No one else has observed anything of the sort, although the practice of administering large doses for weeks consecutively is common enough.‡ De Mussy, in speaking of his success with this remedy in diarrhœa, states that

* T. S. TRAILL—*Outlines of a Course of Lectures on Medical Jurisprudence*, 1st Amer. from the 2d Edinburgh Ed., Philadelphia, 1841, p. 130—relates the following case: "A country apothecary gave a patient of mine twelve drachm doses, instead of a drachm divided into twelve doses; the man took 5j the first day, 5iij on the second, and 5ij on the third day, when I was called, and found him suffering extreme pain in his abdomen and throat. He had vomited on the previous evening; his pulse was small, he felt very feeble, and had much anxiety about the præcordia. I gave castor oil, milk porridge, and carbonate of potassa. The man was several days very poorly, but finally recovered." There was no chemical analysis of the drug in this case, but the symptoms are best explained by supposing a contamination with arsenic, such as was actually found in the two following cases: H. S. FULLERTON, of Hillsborough, Ohio—*Case of poisoning by impure nitrate of bismuth*, Amer. Jour. of the Med. Sci., Vol. LXVII, 1874, p. 280—reports that a physician having taken the subnitrate for medicinal purposes experienced, after a day or two, symptoms of gastro-intestinal irritation, and observed some puffiness about the eyes. Discontinuing the bismuth, these symptoms disappeared, but they recurred when it was resumed. Chemical analysis demonstrated the presence of a formidable proportion of arsenic. Finally, L. HEBERT—Le Mouvement Médical, Nov. 22, 1873; the number of this Journal cited is not in our library, and I borrow the account from a note appended to the last case by the Editor of the Journal—has reported a case in which symptoms of poisoning were developed in an infant taking subnitrate of bismuth, and in which arsenic was recognized in the medicine by chemical analysis.

† See the accounts of gastric uneasiness, &c., occasionally noticed after the administration of medicinal doses by POTT—note *, p. 788, *supra*; ODIER—note §, same page; and others. WERNECK—*Erscheinungen, welche das Bismuthum nitricum oxydatum album seu Subnitras Bismuthi bey gesunden Menschen hervorgebracht hat*, Med.-chirurg. Zeitung, 1831, Bd. III, S. 312 *et seq.*—gave from 6 to 40 grains daily to healthy subjects, and reports that it produced gastric uneasiness, headache, giddiness, circulatory disturbance, sometimes diarrhœa; in very large doses it sometimes excited vomiting, but this effect was quite uncertain. G. GIACOMINI—Vol. VII, p. 171, *op. cit.*, p. 754, *supra*, also p. 478 of the French translation, cited on the same page—states that he himself took daily 10 to 40 centigrammes of the subnitrate of bismuth in pill form before breakfast. The only sensible effect was a sensation of hunger or rather of emptiness of stomach, which was readily calmed by a little food, but which was only temporarily relieved by drinking water or coffee, recurring promptly and with more force to such a degree as to give rise to extreme lassitude; occasionally it appeared to increase the secretion of urine. These descriptions, so far as they represent actual objective observations, must refer to phenomena which either accidentally coexisted, or were produced by arsenical or other contamination of the samples used.

‡ FILIPPO LUSSANA—*Dell'azione del sotto-nitrato di bismuto*, Gaz. Med. Italiana, Lombardia, T. III, 1852, p. 29, (see also Dublin Quart. Jour. of Med. Sci., Vol. XV, 1853, p. 252.)—following the directions of MONNERET, administered the subnitrate of bismuth in large doses to patients affected with tubercular diarrhœa, diarrhœa the consequence of chronic enteritis, gastralgia of long standing and mesenteric disease. He declares that it is true that it did not give rise to intestinal irritation, but states that it did not arrest his cases of tubercular or mesenteric diarrhœa; and I suspect that it was from the progressive cachexia, probably complicated with a scorbutic taint from inadequate nourishment, which accompanied the progress of these unarrested cases, that he drew the group of phenomena he supposed to be due to chronic bismuth poisoning. According to his account, patients who continue long the use of large doses of bismuth acquire a leaden aspect; the eyes become sunken and present a livid subpalpebral circle; the breath becomes offensive; the gums swell, grow livid and discharge a sanious blood; hæmorrhage is easily excited, and sometimes profuse passive hæmorrhages arise. No one else has made similar observations. MONNERET—see note *, p. 789, *supra*—who has used the drug so freely, never saw anything of the sort, nor have any similar phenomena ever been observed by TROUSSEAU or others, who in modern times have done the same. I myself have, in thousands of patients suffering with fluxes during our civil war, who, however, had never taken any bismuth, seen phenomena quite similar to those described by LUSSANA; but I have never seen any similar results ensue upon the long continued use of bismuth either in those to whom I have administered it myself or those to whom I have seen it given by others.

in a few cases it has appeared to increase the diarrhœa instead of diminishing it.* In my own earlier trials I sometimes observed the same thing; nay, as elsewhere reported, during the civil war I witnessed a few cases in which its administration for diarrhœa was followed by tormina, tenesmus and other dysenteric phenomena.† But this effect I have still oftener observed to follow the premature checking of an acute diarrhœa by opium or astringents; and since I have learned to exercise due discretion as to the time when bismuth may be first administered, I have ceased to encounter such accidents.

The sole value then of the reported cases of poisoning, or other injurious effects from the administration of this medicine, is that they emphasize the importance of avoiding the use of carelessly prepared or sophisticated samples. The contamination with arsenic is especially to be dreaded. The chemical analyses of samples offered for sale to the Medical Department of the United States Army during the last few years show that the presence of a trace of this poison is exceedingly common, and that occasionally more considerable quantities are present. It is true that, except in a small number of cases, the proportion of arsenic has not been sufficiently great to constitute a serious source of danger, but its presence is evidence of discreditable carelessness on the part of the manufacturers; and it would be well for pharmacists and physicians to adopt the rule of our laboratory, and inflexibly refuse to purchase any samples that contain the slightest trace of arsenic, or from which distilled water abstracts any recognizable soluble matters.‡

When the character of the local action of subnitrate of bismuth upon the alimentary mucous membrane is taken into consideration the limitations of its usefulness in the fluxes will readily be understood. It would seem worse than useless to resort to such a medicament during the active progress of diphtheritic dysentery, and, although it has sometimes appeared to do good during the early stages of catarrhal dysentery, it may well be questioned whether it would not often prove injurious if habitually resorted to in such cases as a sub-

* DE MUSSY—*loc. cit.*, note †, p. 789, *supra*. † *Circular No.* 6, p. 126, *op. cit.*, p. 571, *supra*.

‡ The danger of arsenical contamination was especially insisted upon by TROUSSEAU—T. II, p. 753, *op. cit.*, p. 716, *supra*. According to TAYLOR—*loc. cit.*, p. 791, *supra*—it is of common occurrence in the subnitrate used in England. It has happened in the Laboratory of the Surgeon General's Office that, of a dozen samples offered to the department by different dealers on a single occasion, *all* have been rejected on account of this impurity. The rule adopted by our chemist, Dr. WM. M. MEW, is to filter distilled water through one portion of the sample and evaporate the filtrate to dryness; another portion is tested for arsenic. All samples which yield a perceptible trace of arsenic or of residue from the filtrate are rejected. Yet we have always been able to purchase any quantity of the pure drug; and if others would follow our example, the contaminated article would disappear from the American market. For the convenience of country physicians and druggists, I mention the very simple means of testing qualitatively for arsenic recommended by Dr. MEW: The materials required are fragments of chemically pure zinc, chemically pure muriatic acid, corrosive sublimate, distilled water, test-tubes, a spirit-lamp and some cotton-wool. Half a teaspoonful of the sample of bismuth to be examined is introduced into a test-tube with a fragment of zinc; the tube is filled about a third full with a mixture of one part of muriatic acid to five of distilled water, and a plug of cotton-wool introduced loosely into its mouth to prevent the mixture from splashing over. It is then gently heated over the spirit-lamp. If any arsenic be present, arseniuretted hydrogen is generated, which is recognized by holding over the mouth of the tube a piece of filtering paper moistened with a solution of one part of corrosive sublimate to twenty parts of distilled water; a yellow stain is produced if arsenic be present. That the chemicals are all free from arsenic can be demonstrated by repeating the operation in another test-tube without the bismuth. The possibility of an injurious contamination with selenium and tellurium has recently been indicated by E. A. LETTS—*Some bismuth residues*, The Pharmaceutical Jour. and Transactions, London, Nov., 1878, p. 405: See also the report of the discussion of this paper in the Pharmaceutical Society—*op. cit.*, p. 417. Examining the residues of some commercial bismuth from Australia, LETTS detected the presence of betwen 12 and 20 per cent. of tellurium, besides selenium, gold and silver, and arrived at the conclusion that these residues "consist in all probability of a mixture of tellurides and selenides of the metals gold, silver and bismuth." In the course of the discussion of this paper Prof. ATTFIELD stated "that a very disagreeable odour was communicated to the breath and probably to the skin of some patients who took preparations of bismuth. Mr. Brownen had stated that a sample of carbonate of bismuth which had caused these unpleasant effects contained tellurium, so the public, or at any rate, certain newspaper writers had jumped to the conclusion that the fœtor was due to the tellurium, but this was not yet proved." He asked if any such effect had been observed to follow the use of the preparations made from the sample of bismuth which yielded these residues. Mr. SCHACHT, who had furnished Mr. LETTS with the residues, stated that "he had not the slightest doubt that the preparations did contain something that caused these unpleasant symptoms. Some of the accounts he had received were scarcely credible, and he could not think that the whole of the effects said to be caused by an exceedingly small dose of tellurium were due to that cause. A fellow pharmacist had told him that he had given to his daughter, a little girl of about six years of age, a dose of this bismuth, and that it had made her breath smell of garlic for more than a week." Mr. J. S. TAYLOR called attention to lead as another impurity of bismuth. Lead has also been signalized, as an adulteration of the subnitrate of bismuth sold in the shops of Paris, by A. CARNOT—*Note de l'oxyde de plomb dans le sous-nitrate de bismuth des pharmacies*, read to the Acad. des Sci., March 18, 1878; I cite Gaz. Hebdomadaire, T. XV, 1878, p. 199—who found many samples which contained from one to three parts to the thousand, while others yielded to analysis as much as .6 to 1 per cent. The subject was subsequently investigated by A. RICHE—*Rech. sur le sous-nitrate de bismuth*, Bull. de l'Acad. de Méd., T. VII, 1878, p. 741—on behalf of the School of Pharmacy of Paris, who asserts that he found but a single sample in which the quantity exceeded one part to the thousand; in that the quantity was between three and four parts per thousand. These observations show the importance of the whole subject of bismuth adulteration, which is by no means satisfactorily disposed of when arsenic is excluded.

stitute for appropriate evacuants. Accordingly, Savignac earnestly protests that, although it is one of our best remedies in diarrhœa, it is not an antidysenteric, and insists that it should not be given in dysentery until the first violence of the attack is past, and the flux, assuming the characters of diarrhœa, threatens to become chronic.* Nor does it seem advisable to resort to this, any more than to other medicines, for the purpose of at once restraining the flux in the early stages of acute diarrhœa, especially if it be accompanied by severe gripings, abdominal tenderness or fever. By so doing we shall always run the risk of converting the diarrhœa into dysentery; perhaps, even, if we persist, of causing the dysentery to take on the diphtheritic character.

The true field for the operation of this admirable remedy is in painless diarrhœas after the use of evacuants, and in chronic fluxes. But in such chronic fluxes as we too often observed during the civil war, in which the constitutions of the victims were tainted with malaria and scurvy, and their thickened colons riddled with innumerable ulcers, how vain to hope to restore health merely by the administration of this or any other drying remedy. Change of air, suitable diet and appropriate constitutional treatment are indispensably demanded in such cases, and without their help no reasonable hopes for the success of any purely local remedies can be entertained; but if these general measures be duly employed, I do not doubt that bismuth is a valuable auxiliary, potent in dealing with the local affection. I accept the opinion of Brassac,† that by its use we can favor the cicatrization of intestinal ulcers; only, in these cases, still more than in fluxes uncomplicated by intestinal ulceration, we shall waste time if we give it in little doses. Monneret has justly ridiculed the attempt to obtain its local effects in any marked degree, on a surface so extensive as that of the alimentary mucous membrane, by the pitiful quantities with which some physicians are content;‡ but I incline to think that he has gone somewhat too far in this direction. In the great majority of suitable cases the flux can be restrained by a drachm or two of the drug daily; yet where it is clearly indicated, and these doses seem insufficient, I do not hesitate to follow the example of the French physician.

Most of the combinations with which it has been hoped to increase the efficacy of this drug should be regarded with distrust. The addition of calomel must be censured as an inexcusable error. As for opium, I incline to the view that in most of the cases in which it is indicated, bismuth should not be prescribed until the symptoms which require the anodyne have subsided. I do not regard with favor its combination with vegetable astringents, and the addition of the soluble mineral astringents is not to be thought of. The combination with an equal quantity of precipitated carbonate of lime, commended by Trousseau,§

* SAVIGNAC—p. 405, *op. cit.*, p. 620, *supra*. BARRALLIER—p. 782, *op. cit.*, p. 603, *supra*—after relating the observations of BRASSAC and MAILLOT—see note §, p. 789, *supra*—declares that he has never employed the subnitrate of bismuth in acute dysentery.

† BRASSAC—p. 286, *op. cit.*, p. 789, *supra*—gives in support of his view an account of an autopsy performed on a patient dead of chronic dysentery and phthisis. This man had vainly taken the subnitrate of bismuth during the last few days of his life; the frequency of the stools was diminished, but he finally succumbed. On dissection four recent cicatrices, about the size of fifty-centime pieces, were found at the junction of the colon and rectum, as well as other ulcers in which the process of repair had evidently commenced. I do not regard this case as by any means conclusive, in view of the circumstance that cicatrices and cicatrizing ulcers are occasionally observed in fatal cases of chronic dysentery in which bismuth has not been given; nevertheless I have adopted, on the basis of clinical observation, the view of the author that bismuth favors the cicatrization of intestinal ulcers. I cannot agree with SAVIGNAC—*loc. cit.*, *supra*—when he writes of chronic dysentery, "je me croirais bien désarmé contre cette forme grave de la maladie si je n'avais pas d'autre médicament à ma disposition," if he intended by this expression to throw discredit on its use.

‡ MONNERET—T. LXXI, p. 482, *op. cit.*, note *, p. 789, *supra*.

§ TROUSSEAU—T. III, p. 113, *op. cit.*, p. 664, *supra*. I note that my friend Dr. JAMES E. REEVES, of Wheeling, West Virginia—*Medical notes*, The Medical Times, Vol. I, 1870-1, p. 315—advises a combination of bismuth, prepared chalk and Dover's powder, as the sole treatment in dysenteries preceded by diarrhœa: "Neither catharties nor laxatives are to be administered, but the following powder is given in a teaspoonful of the tincture of cinnamon every four or six hours: ℞ Bismuth. subnit., gr. xvj-xxx; cretæ præparatæ. gr. x-xv; pulv. ipecac. comp., gr. iij-vj. M. One-half to one grain of powdered opium may be either added to or substituted for the Dover's powder." The dysenteries in which this treatment gave "so much satisfaction" must have been mild catarrhal forms. FONSSAGRIVES—T. IX, p. 538, *op. cit.*, p 790, *supra*—speaks with commendation of the combination of the subnitrate of bismuth with magnesia, which I have not tried. I should prefer to use the magnesia, if indicated, separately.

is far less objectionable, and may perhaps prove occasionally useful in cases in which there is much gastric acidity, but it will generally be found that the mixture is less efficient than an equal quantity of bismuth given by itself.*

The *subcarbonate of bismuth*, regarded by Hannon of Brussels, as preferable to the subnitrate in gastralgia accompanied by an excess of acid in the stomach,† has sometimes been employed as a substitute for the subnitrate in the treatment of the fluxes. It was issued for this purpose to a limited extent during our civil war,‡ some of the medical officers regarding it as of equal efficacy, while others thought it inferior.§ I myself have had no experience with it. As for the soluble preparations of this metal, especially the *citrate of bismuth and ammonia*,‖ they are only named here that the reader may be warned against trifling with them. None of the good effects possessed by the subnitrate, in virtue of its insolubility, can be expected from them, and their use involves dangers which the prudent physician will avoid.

TONICS.—During convalescence from acute fluxes and the progress of chronic cases, the use of tonics is not unfrequently indicated. Of the *vegetable bitters*, suitable for this purpose, with which the Greek physicians were acquainted, a few, such as *gentian* and *chamomile*,¶ still survive, or are at least represented in modern pharmacy by allied plants.

* In this place I may refer to the *crème de bismuth* of QUESNEVILLE: see a letter by P. GAUBERT—*Sur l'emploi du sous-nitrate de bismuth, broyé et en pâte, sucré et aromatisé*, Le Moniteur Scientifique, T. II, 1859-60, p. 369; an article entitled *De la crème de bismuth contre la diarrhée*, same Jour., T. V, 1863, p. 599, and other laudations in the same Jour., T. VI, 1864, pp. 563 and 1157, T. X, 1868, pp. 891 and 1003. This preparation I understand to be simply the subnitrate suspended in water, with sugar and aromatics to give it an agreeable taste. I have never seen it; nor have I ever found any difficulty in getting even children to take the subnitrate without repugnance if a little sugar is added to it, so that I have felt no necessity for such a preparation.

† See an article entitled *De la préparation et de l'emploi thérapeutique du sous-carbonate de bismuth* in the Bull. Gén. de Thér., T. LII, 1857, p. 110. According to FONSSAGRIVES—p. 534, *op. cit.*, p. 730, *supra*—TROUSSEAU and PIDOUX, in the 7th Ed. of their *Traité de Thér.*, T. I, p. 208, which I have not been able to see, take a similar view. Among more recent writers I note that H. C. WOOD—p. 39, *op. cit.*, p. 675, *supra*—takes the ground that the actions of this preparation and the subnitrate are "so exactly similar that they can practically be considered as one thing."

‡ According to the report of Surgeon W. C. SPENCER, cited p. 708, *supra*, the total quantity of subcarbonate of bismuth purchased during the civil war was 132,963 ounces; but these figures include also all the subnitrate purchased. That neither preparation proved very efficacious during the war will be readily understood when it is stated that both were generally issued in 2-oz. bottles, that the quantity allowed general hospitals by the supply table was but 32 ounces yearly for a command of 1,000 men, and that none was authorized by the field supply table.

§ I have heard a great diversity of opinions expressed by medical officers in conversation on this subject, and confess I have been influenced by what I have heard to distrust the efficacy of the subcarbonate, perhaps unjustly.

‖ This preparation was first introduced, under the name of *liquor bismuthi*, by SCHACHT, of Clifton, England: See an article entitled *Chemical products and pharmaceutical preparations*, The Lancet, 1863, Vol. II, p. 49; also C. R. C. TICHBORNE—*Upon the administration of bismuth in the soluble form*, Pharmaceutical Journal and Trans., Vol. V, 1863-4, p. 301—with the appended remarks of SCHACHT and others, made when the paper was read in the Pharmaceutical Society. See also the method for compounding this preparation suggested by N. G. BARTLETT, of Chicago—*Bismuthi et ammoniæ citras*, Amer. Jour. of Pharmacy, Vol. XIII, 1865, p. 1. According to H. C. WOOD—p. 41, *op. cit.*, *supra*—this preparation "has the marked disadvantage of being irritant in large doses." The *tannate of bismuth* was introduced by CAP—*Note sur le tannate de bismuth*, Bull. de L'Acad. Imp. de Méd., T. XXV, 1859-60, p. 125—who reports that it has been used in diarrhœa with success by DEMARQUAY, ARAN, BOUCHUT and others. This preparation of bismuth is said to be quite insoluble, and therefore is not liable to the objections urged against the citrate. Is it better than the subnitrate, or as good? I have not been able to find published evidence to decide this question, and have never tried it myself. I see in the advertisement sheets of the American journals the titles of various elixirs of bismuth combined with calisaya bark, iron, strychnia, pepsin, or several of these ingredients; granular effervescent salts containing citrate of bismuth with pepsin, iron or strychnia; besides sundry lozenges, pills, &c., in which bismuth is similarly combined. I have no confidence in any of these preparations, and especially advise that all those in which the bismuth is in solution should be avoided.

¶ *Gentian*, the root of the *gentiana lutea*, has been supposed to be the same as the Γεντιανή of the Greek physicians: See DIOSCORIDES—Lib. III, Cap. 3, fol. 137. Ed. cited p. 623, *supra*; GALEN—*De simp. med. temp. ac fac.*, Lib. VI, Cap. 3. [Ed. Kühn, XI, 856;] and PAULUS ÆGINETA—Lib. VII, Cap. 3, Vol. III, p. 82, *op. cit.*, p. 624, *supra*. This drug was valued by the Arabian physicians also—compare EBN BAITHAR, T. I, p. 260, Ed. cited p. 704, *supra*—and had from the first the reputation of possessing alexipharmic properties, for it entered into the composition of the antidote of MITHRIDATES and the theriaca of ANDROMACHUS. That the doctors of the seventeenth century still held to these views may be seen in the work of DALE—p. 182, *op. cit.*, p. 729, *supra*—in which its virtues in plague and other venomous affections are lauded. For its more modern history, see especially ALSTON—T. I, p. 449, *op. cit.*, p. 772, *supra*; MÉRAT et DE LENS—T. III, p. 300, *op. cit.*, p. 788, *supra*; and the *Pharmacographia*, p. 389, Ed. cited p. 704, *supra*. The authors of the latter work express doubts whether the gentian of the Greek physicians was the species at present employed. It is probably impossible to arrive at a positive conclusion on this head. Among those who have employed this drug in the fluxes I may particularly mention TWINING—*loc. cit.*, p. 695, *supra*—who used the extract of gentian as an ingredient of his pills of ipecacuanha and blue mass. Under the designation *chamomile*, the flowers of *anthemis nobilis* are intended by the United States and British Pharmacopœias. DIOSCORIDES—Lib. III, Cap. 154, fol. 188 and 189, *op. cit.*—described three genera of Ἀνθεμίς. GALEN—*De simp. med. temp. ac fac.*, Lib. VI, Cap. 1. [Ed. Kühn, XI, 833.] and PAULUS ÆGINETA—Lib. VII, Cap. 3, Vol. III, p. 408, *op. cit.*—mention only one. AVICENNA—Lib. II, Tract. 2, Cap. 121, p. 286, *op. cit.*, p. 632, *supra*—on the other hand, like DIOSCORIDES, describes three kinds, distinguished by the color of their flowers. ADAMS, in his commentary on PAULUS—*loc. cit.*—expresses the opinion that the ancient anthemis or chamæmelum (Χαμάιμηλον, GALEN and PAULUS, *loc. cit.*) certainly embraced our modern chamomile, but probably was not restricted to it. For an account of the varieties used in modern times the reader is referred especially to DALE—p. 96, *op. cit.*; MURRAY—Vol. I, 1776, p. 143, *op. cit.*, p. 752, *supra*; ALSTON—Vol. II, p. 108, *op. cit.*; MÉRAT et DE LENS—Vol. I, p. 314, *op. cit.*; and the *Pharmacographia*, p. 344. ZIMMERMANN attached great importance to chamomile tea in the treatment of dysentery; next to opium he declared it afforded the best means of alleviating the pains—Cap. 5, S. 100, *op. cit.*, p. 648, *supra*. PRINGLE—Part III, Chap. 6, p. 272, *op. cit.*, p. 640, *supra*—held that fomenting the belly with chamomile tea and taking it internally was even better for mitigating the gripes and expelling wind in dysentery than opiates, which only palliate and often augment the cause. He regarded chamomile, like serpentaria, as possessed of antiseptic powers.

Still greater importance has been attached to certain vegetable bitters imported from the East and West Indies during the seventeenth and eighteenth centuries, among which *simaruba*, *cascarilla*, *quassia*, *calumba* and *serpentaria* may be particularly mentioned. Some of these drugs, especially simaruba and calumba, enjoyed during the last century a short-lived reputation as specifics in dysentery;* but modern physicians very generally recognize that they exercise no restraining influence upon the fluxes, and are valuable only when it becomes desirable to stimulate the flagging appetite and to endeavor to restore the exhausted strength of convalescent and chronic cases.† Often administered in infusion and decoction, they are also frequently employed to medicate wines and alcoholic liquors, and should then be administered with all the precautions advisable when alcoholic drinks are employed by themselves.

---

* *Simaruba* is the bark of the root of *s. officinalis*, (De C.,) a tree growing in Guyana and the West Indies. According to DE JUSSIEU—*Rech. d'un specifique contre la dyssenterie, indiqué par les anciens auteurs sous le nom de Macer, auquel l'écorce d'un arbre de Cayenne, appellé Simarouba, peut être comparée et substituée;* I cite from PLANQUE'S *Biblioth. Choisie de Méd.*, T. IV, Paris, 1753, p. 14, and the *Collect. Académique*, Partie Françoise, T. VI, 1781, p. 503—some of this bark was first brought from Cayenne to Paris about 1713, with the statement that the natives of Cayenne used it successfully in diarrhœa and dysentery. It was given to the Academy of Sciences and to FAGON, physician to the king, for trial; but the quantity was small, most of it was preserved as a curiosity, and nothing was learned, except that it was not dangerous, until 1718, when the very hot summer was followed by a good deal of dysentery, for which the little of the drug that remained was tried with success, after the failure of ipecacuanha and other remedies. Thereupon DE JUSSIEU made arrangements for further importation, and, in 1723, BARRERE having on his return from Cayenne brought with him fifty pounds of the bark, he used it successfully in bilious and bloody diarrhœas, as well as in obstinate and dangerous dysenteries, in the dose of 5ij in decoction. He admitted, however, that if administered without previous necessary evacuation the constipation it caused proved injurious. DE JUSSIEU fell into the error of attempting to identify this drug with the *macer* which DIOSCORIDES—Lib. I, Cap. III, fol. 45–6, *op. cit.*, last page—declared to be useful in dysenteries and alvine fluxes. The Arabian physicians long before had confounded macer with mace; see the remarks of ADAMS on the macer of PAULUS ÆGINETA—T. III, p. 237, *op. cit.*, last page; see also MURRAY—Vol. III, p. 457, *op. cit.*, p. 752, *supra*. DEGNER—Cap. III, § 42 *et seq.*, p. 149 *et seq.*, *op. cit.*, p. 625, *supra*—following the example of DE JUSSIEU, gave it in the same dose, after appropriate evacuations, in the Nimeguen epidemic, and thought it especially advantageous when the discharges were bloody—p. 155; see also p. 269 and p. 286 *et seq.* ZIMMERMANN dealt with the question of the use of this drug with his usual sagacity; even when he was called in late in the disease—Cap. V, S. 102, *op. cit.*, last page—when, he tells us, simaruba, cascarilla and terra japonica are usually thought absolutely necessary, he gave sometimes an emetic and then relied on rhubarb. He admitted that in chronic cases, especially if the discharges are bloody, simaruba is no bad remedy—Cap. X, S. 496—but declared that in his judgment it does best where the patient merely requires to be strengthened; so long as the bowels harbor any putrid matters it is either useless or injurious—S. 495. PRINGLE—p. 281, *op. cit.*, p. 640, *supra*—informs us that after reading DEGNER'S work he made a few trials of simaruba with favorable results; but he pointed out that it proved salutary only when given in the third stage of the disease, and relates that HUCK, in North America, had arrived at a similar conclusion. J. P. FRANK—Vol. III, p. 452, *op. cit.*, p. 343, *supra*—obtained excellent effects in the latter stages of asthenic dysentery from a decoction of simaruba to which he added cinnamon-water and opium; and HAUFF—S. 417, *op. cit.*, p. 534, *supra*—states that it was used with advantage in the Wurtemberg epidemic. *Cascarilla* is the bark of the *croton eleuteria*, a shrub or small tree growing in the Bahama Islands. It was first brought to Europe some time during the seventeenth century, and was described by J. A. STISSER—*Actorum laboratorii chemici in Acad. Julia specimen secundum*, Helmstadt, 1693, Cap. 9, De cortice eleuterii pro cortice Peruviano China China vendito. DEGNER—Cap. 3, § 54, p. 164 *et seq.*—regarded the use of cascarilla in dysentery with almost as much favor as he did simaruba. He held that it not merely corroborated the relaxed intestines, but moderated the febrile movement and the abdominal pains: he administered the powder or the tincture, usually in combination with rhubarb, catechu, simaruba or other remedies. It has since his time been frequently employed as an aromatic bitter in dysentery and chronic fluxes. *Angustura*, the bark of the *galipea officinalis*, which was not brought into general use until after the publication of the observations of BRANDE in 1791—see the *Pharmacographia*, p. 97, Ed. cited p. 703, *supra*—has also had a limited use for the same purpose. *Quassia*, the wood of the *simaruba excelsa*, (De C.,) was formerly derived solely from the quassia amara, (L.,) an allied shrub or small tree growing in Surinam. The medicinal virtues of the latter were made known in Europe through ROLANDER, who, in 1756, carried some of it to Stockholm; and in 1763, LINNÆUS, with the help of a flowering branch with leaves, &c., brought from Surinam in spirits of wine by DAHLBERG, described the tree botanically. ROLANDER had found it in use in Surinam in the hands of a negro named QUASSI, (or COISSI,) who gave it as a secret remedy in the malignant fevers of that country with such success that he thought it worth while to purchase the secret: Compare C. M. BLOM—*Lignum quassiæ*, (Linné præside,) Amœn. Acad., T. VI. p. 416, and J. A. MURRAY—Vol. III, p. 432, *op. cit.* According to *The Pharmacographia*—p. 118—this Surinam quassia is still employed in France and Germany, but in the London Pharmacopœia it has been superseded by the *picræna excelsa*, (Lindl. s. excelsa, De C.,) which is officinal in our own Pharmacopœia. MURRAY—p. 449, *op. cit.*—cites some accounts of its use in diarrhœa and in lienteries succeeding dysentery, but it never shared the great reputation of simaruba in the latter disease. *Calumba*, (columbo,) the root of the *jateorhiza palmata*, (MIERS,) *cocculus palmatus*, (De C.,) a native of Mozambique and other parts of Africa, was brought to Europe by the Portuguese in the 17th century, and is mentioned by FRANCESCO REDI—*Esperienze intorno a diverse cose naturali*, &c., Florence, 1671; I cite from a modern reprint of his *Opere*, Vol. IV, Milan, 1811, p. 119—as an alexipharmic worthy of further trial. Among the natives of Eastern Africa it enjoyed the reputation of being beneficial in various diseases, among others dysentery, and during the last century it was brought into use for this and other fluxes in Holland, France and England: see MURRAY—T. VI, p. 154, *op. cit.*, and the *Pharmacographia*, p. 22, *op. cit.* PERCIVAL—Vol. I, p. 296, *op. cit.*, p. 770, *supra*—declared that he had "often observed very salutary effects from its use, in diarrhœas, and even in the dysentery;" and expressed the opinion that it may often be prescribed with safety and advantage in the early stages of these disorders, when astringents would be hurtful. CULLEN—Vol. II, p. 78, *op. cit.*, p. 740, *supra*—however, referring to PERCIVAL'S essay, remarks that, so far as he could learn, its employment in dysentery "has not prevailed in Britain." *Serpentaria* or *Virginia snakeroot*, the root of *aristolochia serpentaria*, was first brought to the notice of European physicians by THOMAS JOHNSON in his edition of GERARDE'S *Herball*, published in 1636. (ALSTON—T. I, p. 520, *op. cit.*, p. 772, *supra*—and MURRAY—T. I, p. 348, *op. cit.*—say 1633; I have followed the date given in the *Pharmacographia*, p. 532, which agrees with the date of the edition referred to as given in the *Biographie Universelle*, T. XVII, 1816, p. 176. Our library does not possess the edition.) Like other drugs, mentioned in this and the previous note, it was at first regarded as an alexipharmic. According to DALE—p. 194, *op. cit.*, p. 729, *supra*—it cures the bites of mad dogs, averts hydrophobia, and is the most certain and immediate remedy against the bites of venomous serpents. PRINGLE employed a decoction of it in dysentery complicated with the hospital fever—Part III. Chap. 6, p. 274, *op. cit.*—combining it commonly with Peruvian bark and laudanum, or at other times, "and especially when the pulse was sunk," merely adding to it some of the theriaca of ANDROMACHUS; he used it also in hospital fevers without dysenteric complication—p. 311—and regarded it as a powerful antiseptic—see *Appendix*, pp. xii. xx, xxvi and xxvii.

† Compare, for example, the well expressed views of SAVIGNAC—p. 393, *op. cit.*, p. 620, *supra*, and STILLÉ—pp. 375 and 379, *op. cit.*, p. 650, *supra*—with regard to the use of the vegetable bitters in the fluxes.

But by far the most important of the vegetable tonics employed in these diseases is *Peruvian bark* and its precious alkaloid *quinia*.* Richard Morton relied chiefly upon this bark, in combination with opium, in the diarrhœas and dysenteries that prevailed in London from 1666 to 1672, and which he regarded as masked forms of intermittent fever.† Torti (1709) boldly employed it in the dysenteric and atrabiliary fluxes, which he held to be manifestations of pernicious fever.‡ Almost all those subsequent writers who have believed malaria to be one of the chief causes of diarrhœa and dysentery have followed the example of these physicians, and have used the bark or its alkaloid in all the fluxes they have attributed to this endemic influence.§ Moreover, since the time of Hoffmann, many physicians who have refused to adopt this etiological view have nevertheless resorted to the bark as a tonic and supporting remedy in the appropriate stages of the fluxes;‖ while the reputation it acquired during the early part of the eighteenth century in the treatment of low fevers, and as a means of combating putridity of the humors, led Tissot, Zimmermann, Pringle, Robert Whytt, Donald Monro and others to employ it in the adynamic forms of dysentery and in dysenteries complicated with hospital fever.¶

But it did not take its place among the recognized remedies for the fluxes without loud opposition. Degner declared that certain military surgeons by its use, or rather abuse, had killed whole companies of their soldiers;** and Broussais asserted that during the French campaign of 1806 in Germany he found that Peruvian bark as well as the other bitters were not well borne in intermittent fevers complicated with fluxes.†† All such opposition, however, has been silenced by accumulated experience; since the successful isolation of quinia that alkaloid has come more and more into use as a substitute for the bark in most

* The story of the introduction of *cinchona bark* into European medicine can only be alluded to here. It began to attract notice during the first half of the seventeenth century. LOPEZ DE CANIZARES, the Spanish corregidor of Loxa, is said to have been cured of a fever by it in 1630, and hearing in 1638 that the Countess of Chinchon, wife to the viceroy of Peru, was suffering with an obstinate tertian, he sent her physician, JUAN DE VEGA, a package of the bark, which speedily restored her to health. The countess became an active advocate of the new remedy, and caused its distribution to such an extent that it acquired the name of *The Countess' Powder*. It speedily found its way to Europe, where it was long known as *The Jesuits' Powder*, on account of the active part taken by that religious organization in distributing it and favoring its employment. For an account of the fierce battles waged between its advocates and the more conservative physicians of the age, I must refer the reader to the numerous historical works on the subject. I regret to say that some of the most important of these have not yet found their way to our library. Not only do I miss the earlier works of J. J. CHIFFLET—*Pulvis febrifugus orbis Americani ventilatus*, Paris and Louvain, 1653, and of ROBERT TALBOR (or TABOR)—*Pyretologia, a rational account of the causes and cure of agues*, London, 1672—who did so much afterwards towards popularizing the remedy in England, but even such modern treatises as that of MARKHAM—*Chinchona Species of New Granada*, London, 1867. The reader will find summary historical accounts with references to the literature in the work of J. F. MAUTI—*Diss. de cortice Peruviano*, Leyden, 1760; I cite the reprint in SANDIFORT'S *Thesaurus dissertationum*, Vol. I, Rotterdam, 1768, p. 175; MURRAY—T. I, p. 546, *op. cit.*, p. 752, *supra;* MÉRAT et DE LENS—T. V, pp. 594 and 615, *op. cit.*, p. 788, *supra;* STILLÉ—Vol. I, p. 495, *op. cit.*, p. 711, *supra;* and the *Pharmacographia*, p. 304, Ed. cited p. 703, *supra*. *Quinia* and *cinchonia*, the most important of the alkaloids of Peruvian bark, were not isolated as separate bases until 1820 by PELLETIER and CAVENTOU—*Rech. chimique sur les quinquinas*, Annales de Chim. et de Phys., T. XV, 1820, p. 289. For an account of these and the other alkaloids, with a good bibliography, I may refer to the work of the HUSEMANNS—S. 283, *op. cit.*, p. 766, *supra*.

† RICHARD MORTON—*op. cit.*, p. 399, *supra:* for an account of this epidemic see p. 420 *et seq.* He gave in the dysenteric cases 5j of the bark and gr. j of the solid laudanum of the London Pharmacopœia every four or six hours—p. 425. This was his usual treatment for that protean disease, intermittent fever, when it put on the type of simple vomiting, cholera morbus, torminous diarrhœa or dysentery, as well as in its ordinary forms—pp. 83–4.

‡ TORTI—*loc. cit.*, p. 399, *supra*.

§ Consult the authorities cited in discussing the complication of dysentery with malarial fever—p. 399 *et seq.*, *supra*.

‖ HOFFMANN—T. III, p. 156, *op. cit.*, p. 681, *supra*—approved of the use of Peruvian bark in dysentery after the noxious material was evacuated and the spasm of the intestine quieted: he used also cascarilla and other tonics for the same purpose.

¶ TISSOT—T. III, p. 27, *op. cit.*, p. 625, *supra*—gave extract of bark with orange-flower water in malignant dysenteries. ZIMMERMANN—Cap. X, S. 471, *op. cit.*, p. 648, *supra*—held that in the advanced stages of dysentery, when, as sometimes happens, the pulse sinks and the strength fails, all the remedies required in the malignant fevers are needed, and above all others Peruvian bark. He censured the views of DEGNER with regard to this remedy as unphilosophical—S. 472. PRINGLE—p. 274, *op. cit.*, p. 640, *supra*—commonly used a decoction of Peruvian bark with Virginia snake-root to which he added a few drops of laudanum, in dysenteries complicated with hospital fever, or in those in which the flux continued until the strength was much impaired. ROBERT WHYTT—*Of the use of bark in dysenteries*, &c., (read before the Philosophical Society of Edinburgh, January, 1761.) Essays and Obs., Phys. and Literary, Vol. III, 1771, p. 366—gave with advantage a decoction of Peruvian bark, to which he added some of the confectio japonica of the Edinburgh Dispensatory, in dysenteries, even of the worst kind, "accompanied with a putrid disposition of the humours, and a malignant fever." DONALD MONRO—p. 89, *op. cit.*, p. 625, *supra*—following the example of MORTON, PRINGLE and WHYTT, all of whom he cites, gave in similar cases the powdered bark in half-drachm doses, or scruple doses of its extract, in connection with "the Mindereri draughts, with four or five drops of the tinctura thebaica." Even CULLEN—T. II, p. 106, *op. cit.*, p. 740, *supra*—admitted that the bark may possibly be employed with advantage "in the advanced state, [of dysentery,] when some symptoms of putrescency appear, or when the disease has changed in some measure into the state of diarrhœa."

** DEGNER—p. 239, note, *op. cit.*, p. 625, *supra:* "Ast ab amico certior factus sum, ultimo belli tempore chirurgos quosdam castrenses ex corticis hujus usu, vel forsan abusu, multos cohortis suæ milites letho dedisse."

†† BROUSSAIS—T. II, p. 594 *et seq.*, *op. cit.*, p. 643, *supra*.

of the conditions in which it was formerly given; and the questions connected with their use have been so fully debated that at the present time I suppose the great majority of practitioners are substantially in accord with regard to the more important indications for the administration of these remedies in the fluxes.

In the first place they are valuable as tonics, and may usually be employed for this purpose whenever tonics are required.* Many physicians will agree with Stillé, that the decoction of Peruvian bark, or Huxham's tincture, is preferable to quinia when a tonic and not an antiperiodic operation is intended;† and whenever the principal object is to spur the flagging appetite, I am willing to accept this view, but I am not disposed to underestimate the purely tonic influence of quinia; and that alkaloid can often be given with advantage when the decoctions would be rejected by the stomach. Not merely in the debility of convalescence and the enfeebled condition that so often accompanies the chronic fluxes, but in the prostration approximating collapse that occurs during diphtheritic dysentery, the administration of quinia is often one of the most important of the supporting measures at our disposal. Vogt, who has urgently insisted upon its usefulness under these circumstances, has correctly pointed out the ease with which it is absorbed from the alimentary canal, and the fact that it rarely irritates the inflamed mucous membrane: his view that it checks the tendency to anæmia and favors the new formation of red blood globules will hardly sustain adverse criticism;‡ but the beneficial effects which he thus endeavors to explain have been repeatedly observed by others. All the reasons that can be brought forward in favor of the use of quinia as a supporting measure in external gangrenous processes apply here; and if its administration not infrequently proves unsuccessful, it is at least one of the best remedies at our command in these unfortunate cases.

In the second place, there is little difference of opinion as to the usefulness of these preparations in fluxes complicated with malarial fever. The bark was recommended for this purpose by Tissot, Cleghorn, John Clark, Cullen, Rollo, Harty and a host of other physicians during the last century and the early part of this;§ while quinia, already brought into use as a substitute by Biermann, has been preferred by Naumann, Hauff, Haspel, Hare, Morehead, Maclean, Aitken, Stillé and many others.‖ The erroneous practice of Tissot,

* I shall not attempt to enumerate the writers who during the present century have praised the use of Peruvian bark or its alkaloid as tonics in the fluxes. The view of HARTY—p. 204, *op. cit.*, p. 732, *supra*—who shrewdly spoke of it as a corroborant, useful "to obviate acute or chronic debility," is substantially adopted by HASPEL—T. II, p. 138, *op. cit.*, p. 621, *supra;* SAVIGNAC—p. 393, *op. cit.*, p. 620, *supra;* BARRALLIER—p. 784, *op. cit.*, p. 603, *supra;* HEUBNER—Bd. II, Abth. 1, S. 548, *op. cit.*, p. 529, *supra;* and many others, most of whom use indifferently quinia or the Galenical preparations of bark for this purpose.

† STILLÉ—p. 375, *op. cit.*, p. 650, *supra*. *Huxham's tincture* here praised, which contained, besides the bark, serpentaria, bitter-orange peel, saffron and cochineal, (the U. S. Pharmacopœia of 1870 omits the last two ingredients,) was described by J. HUXHAM in his *Liber de febribus*, [1739,] Opera, T. II, p. 118, Ed. cited p. 660, *supra*.

‡ VOGT—S. 206, *op. cit.*, p. 645, *supra*. I may add that MALININ—*Ueber den Einfluss der Galle auf die Chininsalze*, Centralblatt für die med. Wiss., Jahrg. VI, 1868, S. 370—supposed that since quinia is precipitated from solution by the bile it can only be absorbed in the stomach, and that whatever reaches the intestine becomes insoluble and is lost with the fæces; but G. KERNER, who has made an elaborate study of the mode in which the drug is absorbed—*Beiträge zur Kenntniss der Chinin-Resorption*, Pflüger's Archiv, Jahrg. II, 1869, S. 200, and Jahrg. III, 1870, S. 93—has shown conclusively that although the precipitate is less soluble than the sulphate of quinia, it is nevertheless capable of being absorbed. And in point of fact, when this preparation is administered instead of the sulphate, the greater part of large doses is excreted with the urine, and only a small portion passes out with the fæces, while in the case of small doses none escapes by the rectum, but all in the urine—Jahrg. III, S. 155. The rapid absorption of quinia from the rectum, long well known clinically, has also been made the subject of experimental demonstration by this observer—S. 158–160.

§ TISSOT—T. III, p. 13, *op. cit.*, p. 625, *supra;* CLEGHORN—pp. 255–56, *op. cit.*, p. 637, *supra*. JOHN CLARK—p. 224, *op. cit.*, p. 709, *supra*—held that "Peruvian bark, from its corroborant, astringent, and antiseptic virtues, seems to be well adapted for the cure of this disease, [dysentery,] especially when it depends on the same causes which produce remittent fevers." But he thought that "it is not near so great a specific in fluxes as in fevers," for although it was attended with the most "wonderful effects" in the putrid flux at Bengal, it failed when he essayed it in the dysenteries he subsequently observed in the Straits of Malacca, China and England. CULLEN—*loc. cit.*, note ¶, last page—taught that when dysentery "puts on a tertian type, and may be considered as a part of the tertian fever, at the same time epidemically prevailing, the bark may become an absolutely necessary remedy." HARTY—*loc. cit.*, note *, *supra;* I cite the opinions of ROLLO from this work—p. 207.

‖ BIERMANN—*Bemerkungen über eine in dem Bezirke meines Physikats im August und September dieses Jahrs herrschende Ruhr-Epidemie, complicirt mit Wechselfieber*, &c., Med. Conversationsblatt, 24 März, 1832, S. 88; NAUMANN—Bd. IV, Abth. 2, S. 94, *op. cit.*, p. 645, *supra;* HAUFF—S. 450, *op. cit.*, p. 534, *supra;* HASPEL—*loc. cit.*, note *, *supra;* HARE—p. 460, *op. cit.*, p. 401, *supra;* MOREHEAD—p. 304, *op. cit.*, p. 657, *supra;* MACLEAN—Vol. I, p. 123, *op. cit.*, p. 657, *supra;* AITKEN—Vol. II, p. 660, *op. cit.*, p. 647, *supra;* STILLÉ—p. 376, *op. cit.*, p. 650, *supra*.

who advised that in this complication, as a general rule, the dysentery should be cured first and the fever combated afterward,* has long since fallen into deserved discredit, and no prudent practitioner will now hesitate to cut short the febrile movement with quinia as speedily as possible.

What is then likely to happen was long ago correctly observed by Cleghorn, who frequently made use of the bark in the periodic dysenteries of Minorca. In some of his cases it effectually put a stop to both the fever and the flux, but in others, although it arrested the fever, the flux continued without much alteration.† Which of these two results is likely to happen in any case will depend in part upon the intensity of the malarial complication, in part upon the severity of the flux.‡ When the intestinal inflammation is severe, or has assumed the diphtheritic characters, it is idle to expect that it will be checked by the arrest of the malarial fever; but even in these serious cases the cure of the febrile movement withdraws a most injurious influence, the continued action of which tends to prolong the flux and increase its unfavorable tendencies. When, however, the flux depends upon a catarrhal inflammation of moderate intensity, the relief afforded by the removal of the malarial complication is often accompanied by its speedy cessation; and it is not surprising that some of those who have witnessed such results should have too hastily concluded that similar effects may be expected from quinia in all cases of dysentery.

This view has been maintained by a number of the physicians in our Southern States, especially by Robert Campbell of Georgia.§ I do not doubt in the least the success reported to have attended the use of quinia in these southern dysenteries, because I do not doubt its utility in cases complicated by the effects of the malarial poison, whether manifested by distinctly periodic fever or by the more subtle and obscure symptoms of chronic malarial cachexia; but I have elsewhere endeavored to show that, although the fluxes may be variously complicated by the operation of the malarial influence, it is not to be regarded as their cause;‖ and if this view be correct we are not justified in expecting more from quinia, even in these cases, than the removal of the malarial complication. Still less are we warranted in relying upon it in uncomplicated fluxes; and in these its substitution for more appropriate treatment cannot fail to be attended with disastrous results.

Quinia becomes also a most important remedy in those chronic fluxes which are complicated by malarial fever, or occur in individuals laboring under the malarial cachexia.¶ In such cases it will often prove quite impossible to check the flux until the malarial element has been eliminated by its means; but in these cases also it is important that it should be regarded as an agent by which we can remove a dangerous complication rather than relied upon on account of any direct influence it may be imagined to exert upon the

* TISSOT—*loc. cit.*, note §, last page: "Quelquefois elle est compliquée avec une fièvre d'accès; il faut guérir premièrement la dyssenterie, et ensuite la fièvre." We must, however, do him the justice to add that he made an exception to this rule if the paroxysms of fever were violent.

† CLEGHORN—*loc. cit.*, note, last page: "The great similitude there is in many respects between tertian fevers and dysenteries, induced me frequently to make use of the bark in the last named disease. When the fever and gripes were regularly exasperated, either every day or every other day at stated periods, it has often effectually put a stop to both; especially if the exacerbation began with chillness, and terminated in sweats: At other times it removed the fever, the flux continuing without much alteration."

‡ STILLÉ—*loc. cit.*, note ‖, last page—has observed: "Dysentery complicated with periodical fever is amenable to quinia in proportion to the predominance of the periodical type;" but this view only takes into account the malarial factor, as though the intestinal lesion were of no consequence.

§ R. CAMPBELL—*loc. cit.*, p. 402, *supra*. This able practitioner formulates his leading idea in the following emphatic language: "But what we say is; GIVE QUININE IN DYSENTERY"—Vol. XIV, p. 81, *op. cit.* The capitals are his own. It would do him injustice not to add that he attaches importance to other remedies, especially to oil of turpentine, laxatives, rest and supporting measures, but he places quinine in the first rank: "Quinine should be given *unconditionally*, and irrespectively of the other elements of treatment"—p. 76, *op. cit.* The italics are his own. See also the papers of H. W. DAVIS, GREENSVILLE DOWELL and others, cited on p. 402, *supra;* and that of R. L. PAYNE, of Lexington, N. C.—*Dysentery, its treatment by opium, ipecac and quinine*, Virginia Med. Monthly, Vol. III, 1876, p. 430—who doubtless speaks on the basis of accurate observation when he writes: "I live in a malarious section of country, and I find that many of my flux patients will not improve until I give them quinine"—p. 433.

‖ See pp. 287, 398 *et seq.*, 414 *et seq.*, 495 and 637, *supra*.

¶ Compare the intelligent views of S. H. WARD, physician to the Dreadnought hospital—*op. cit.*, p. 697, *supra*—on this subject.

intestinal lesions.* Both with a view to its tonic effects and as a means of combating the malarial complications which so frequently existed, quinia was extensively employed in the treatment of the fluxes during our civil war.† Some of our medical officers took the view that the malaria of the regions in which our armies operated was the immediate cause of the fluxes observed; others regarded it as merely a complication of the intestinal disorders generated by other influences. Both classes resorted to quinia with a liberal hand. It cannot be pretended that it was always discreetly used, that it was not often withheld when sorely needed and lavished when other remedies would have been of greater service; but on the whole, I suspect the sins of omission were greater than those of commission, and that the errors of those who gave it to excess were among the most pardonable and least injurious of the therapeutical errors of the war.

In addition to the foregoing long recognized indications for the use of quinia in the fluxes, several others have been brought into prominence during the last few years which deserve brief notice in this place. One of these is based upon the power possessed by this alkaloid of diminishing abnormal temperature in fever. Vogt, Wachsmuth, and especially Liebermeister, have drawn attention to this effect of the drug, and have been the means of introducing its extensive use in typhoid and other continued fevers as a potent method of controlling the abnormal temperature.‡ The reality of this influence must be admitted to be firmly established by trustworthy testimony. It does not appear to cut short the

* The occasional success of quinine in chronic cases in which the malarial element is obscure is well calculated to mislead the unwary: See, for instance, those reported by A. FERRAND—*Diarrhée chronique datant de neuf mois traitée sans succès par les moyens ordinaires, guérie subitement par le sulfate de quinine*, Bull. Gén. de Thér., T. LXXVII, 1869, p. 20; and JULES SIMON—*Cas rare de diarrhée, datant de vingt ans*, &c.; *nouvel emploi du sulfate de quinine et nouvel et rapide succès*, &c., Bull. et Mém. de la Soc. Méd. des Hôpitaux de Paris, T. VI, 1869, p. 74.

† See, in illustration of the freedom with which it was administered, the reports in Section II, cited on p. 403, *supra*, as affording testimony to the frequency of malarial complications, as well as the reports of WOODWARD—p. 51, *supra;* HOLSTON and READ—p. 66; BRADLEY—p. 67; PEASE—p. 69; WHITTINGHAM—p. 70; FOYE—p. 73; WOOD—p. 74; MCKELWAY—p. 76; BROWN and CADY—p. 77; MULFORD—p. 80; BIGELOW—p. 83; TUTTLE—p. 90; PYLE and HOFF—p. 91; MORSE—p. 92; COOK—p. 93; COFFMAN—p. 97; BATES—p. 99; and READ—p. 100. See also the paper of W. C. OTTERSON, Surgeon, U. S. V.—*Diseases in camp. Their causes and treatment*, The American Med. Times, Vol. VI, 1863, p. 135—who remarks: "The periodic diarrhœa is purely of malarious origin, and to be treated accordingly: quinine and iron is the best combination." When it is remembered that very nearly a million cases of ague and about half a million cases of remittent and continued fevers were reported to the Surgeon General's Office during the war—see the First Medical Volume, Tables C and CXI—and that bark and quinia were used not only in these but many other morbid conditions, it will be understood that the statement throws no light whatever on the quantity employed in the fluxes; yet it is not without interest in this connection to learn from the report of Surgeon W. C. SPENCER, cited p. 708, *supra*, that the following figures represent the purchases by the Medical Department during the war: Calisaya bark, powdered, 259,258 oz.; fluid extract of cinchona, 518,957 oz.; sulphate of quinia, 595,544 oz.; pills of sulphate of quinia, (1 to 3 grs. each.) 392,970 dozen; citrate of quinia and iron, 50,772 oz.; sulphate of cinchonia, 343,226 oz. These figures represent over 19 tons of sulphate of quinia and about half as much sulphate of cinchonia besides the other preparations.

‡ W. VOGT—*Ueber die fieberunterdrückende Heilmethode (Methodus antipyretica), und ihre Anwendung bei acuten Krankheiten überhaupt*, Schweizerische Monatschrift für praktische Medizin, Jahrg. IV, Mai–Juli, 1859, S. 149 u. 213. A. WACHSMUTH—*Typhus ohne Fieber?* Archiv der Heilkunde, Jahrg. IV, 1863, S. 55. C. LIEBERMEISTER—*Ueber die antipyretische Wirkung des Chinin*, (with 58 illustrative temperature curves,) Deutsches Archiv für klin. Med., Bd. III, 1867, S. 23 u. 569; also his article on *Abdominaltyphus* in ZIEMSSEN's Handbuch, Bd. II, Theil 1, S. 220. LIEBERMEISTER testifies that VOGT (whose work on dysentery—*op. cit.*, p. 645, *supra*—I have frequently quoted) was the first to use quinia in proper doses as an antipyretic in typhoid fever. WACHSMUTH adopted the same method, but LIEBERMEISTER deserves the credit of having established its reputation. He prescribes from 22 to 45 grains of the sulphate or muriate of quinia to be taken within the space of half an hour, and then does not repeat the dose till the next day or the day after, in accordance with the effect upon the temperature, which he expects to be reduced to about the normal standard, 38° centigrade in the rectum. If this does not happen he increases the next dose; if, however, the temperature falls to 37° centigrade or less, he diminishes it. He uses this method in connection with his favorite cold baths, and declares that if he were reduced to the unpleasant alternative of choosing between the baths and the quinia, he should in the majority of cases select the latter. HAGENBACH—*Ueber die Anwendung des Chinin in den fieberhaften Krankheiten des kindlichen Alters*, Jahrb. für Kinderheilkunde, Bd. V, 1871–2, S. 181—adopted the same method with success in the febrile diseases of children; as did also RAPMUND—*Das Chinin in der Kinderpraxis, besonders bei fieberhaften Krankheiten und Keuchhusten*, Deutsche Klinik, Bd. XXVI, Jahrg. 1874, S. 51. The subject has been investigated by C. MURCHISON, E. S. THOMPSON and H. WEBER, as a committee of the Clinical Society of London—*Report of committee appointed to investigate the value of quinine as a means of diminishing bodily temperature and pulse in pyrexia*, Trans. of the Clin. Soc. of London, Vol. III, 1870, p. 201—who, after experiments in typhoid and typhus fevers, pneumonia, measles, scarlet fever, &c., concluded: "That large doses of quinine have a marked effect in reducing the temperature in pyrexia, and a less marked effect on the pulse and respiration"—p. 203. See also the paper of CLIFFORD ALLBUTT—*On the antipyretic action of quinine*, The Practitioner, Vol. XII, 1874, p. 29—who, although he combats the notion that quinia possesses the antiseptic virtues some have assigned to it, (vide *infra,*) is compelled to admit its power in lowering the febrile temperature. Efforts to ascertain by experiment the mode in which this lowering of temperature is effected have been made by P. LEWIZKY—*Ueber den Einfluss des schwefelsauren Chinins auf die Temperatur und Blutcirculation*, Centralblatt für die med. Wiss., Jahrg. VII, 1869, S. 209, and Virchow's Archiv, Bd. XLVII, 1869, S. 352—who has endeavored to show that the effect is produced by a direct diminution of the heat production. B. NAUNYN u. H. QUINCKE—*Ueber den Einfluss des Centralnervensystems auf die Wärmebildung im Organismus*, Archiv für Anat., Phys. und wiss. Med., Jahrg. 1869, S. 526—found that quinine sometimes even succeeded in preventing the rise of temperature that follows section of the spinal cord, but in other instances it failed to have this effect. Similar experiments were made by C. BINZ—*On quinine and alcohol in paralytic fever*, The Practitioner, Vol. V, 1870, p. 4—with like results: "If the conditions of the fever are too favourably constituted, the effect of quinine fails thoroughly." See also the observations of N. JERUSALIMSKY—*Über die physiologische Wirkung des Chinin*, Berlin, 1875, S. 21—as to the influence of quinia on the temperature.

natural course of specific fevers, but by controlling the abnormal temperature diminishes the frequency of intercurrent lesions and increases the chances of recovery. For this purpose it must be given in a single considerable dose, twenty to sixty grains, once in twenty-four or forty-eight hours; the precise quantity to be taken and the frequency of its repetition being regulated after the first dose by observation of the temperature. In view of the rapidity with which it is eliminated by the kidneys,* the effect upon the temperature of such doses, if given at once or at least in divided portions within an hour, will be greater than can be obtained from the same quantity taken at intervals in the course of the twenty-four hours.

The success of this method in typhoid fever and the absence of reliable evidence that it ever produces any injurious effect in this disease show that it may safely be resorted to in dysentery, or other fluxes accompanied by fever, and it appears to be well worthy careful trial in these conditions. In dysenteries complicated by typhoid fever,† as well as when the malarial fevers coexist, this antipyretic influence will doubtless prove serviceable; but in the majority of uncomplicated fluxes, even in diphtheritic dysentery after the early stages, the temperature seldom rises high enough to be itself a source of danger,‡ so that the use of quinia for this purpose will be restricted to a comparatively limited number of cases.

Attention has also been directed recently to the power said to be possessed by quinia of checking tissue-metamorphosis. The testimony on this head is not so accordant as could be wished, yet appears sufficient to render it probable that quinia does operate in this way, although the observations of Unruh show that it sometimes fails to produce this effect in fever, just as it sometimes fails to lower the temperature.§ What is known on the subject must

* The excretion of quinia by the urine, long since recognized by LANDERER—*Untersuchung des Harns eines mit grossen Gaben Chinin behandelten Fieberkranken*, Buchner's Repertorium für die Pharmacie, Bd. LV, 1836, S. 231; VALLÉE—same Bd., S. 380; QUEVENNE—*Note sur la présence dans l'urine de la quinine administrée à haute dose*, Jour. de Chim. Méd., T. IV, 1838, p. 460; P. BRIQUET—*Traité Thér. du Quinquina et de ses Préparations*, Paris, 1853, p. 229—and others, has been made the subject of elaborate investigations by H. M. THAU—*Ueber den zeitlichen Werth der Ausscheidungsgroesse des Chinins bei Gesunden und fieberhaft Kranken*, Inauguraldissertation, Kiel, 1868; and KERNER—*op. cit.*, p. 798, *supra*. THAU, in three experiments on healthy individuals, who had taken altogether 6 grammes of sulphate of quinia, equivalent to 4.4586 grammes of quinia, recovered from the urine within 48 hours 4.3 grammes of quinia, leaving only .1586 gramme unaccounted for. More than a third of the quantity excreted was passed during the first 6 hours, and about three-fourths during the first 12 hours. In three experiments on typhoid patients the same quantity was taken; 4.267 grammes of quinia were recovered from the urine, leaving only .1916 gramme to be accounted for. The proportion excreted during the first 12 hours was about the same as in the healthy cases; the disease appeared to exercise no noteworthy influence on the absorption or elimination of the drug. These observations have been cited by BINZ—*Pharmakologische Studien über Chinin*, Virchow's Archiv, Bd. XLVI, 1869, S. 167—who has apparently, in consequence of supposing the 4.3 grammes excreted to be sulphate as well as the 6 grammes swallowed, erroneously credited THAU with having recovered from the urine a little more than two-thirds of the quantity swallowed only, whereas his figures really represent 96 per cent. And H. C. WOOD—p. 69, *op. cit.*, p. 675, *supra*—has, perhaps in consequence of this discrepancy, been led into the amusing error of supposing the passage just cited from BINZ to refer to a series of experiments by BINZ himself, differing in their tenor from those of THAU. KERNER—Jahrg. III, S. 117, *op. cit.*—holds that a part of the quinia is excreted by the kidneys in a modified form, probably identical with the *dihydrozylquinine* which can be formed out of the body by the oxidation of quinia by means of permanganate of potash; and BINZ—p. 6, *op. cit.*, note ‡, last page—has suggested that, as this substance has no physiological action, the conversion into it of an undue proportion of the alkaloid by excessive oxidation in high fever may account for the failure of quinine to act in some such cases. This speculation, however, is not yet supported by observation.

† As to the frequency of this complication during the civil war, see pp. 288, 403 and 496, *supra*.

‡ See, for example, on the temperature in dysentery, pp. 348 and 351, *supra*.

§ RANKE—*Beobachtungen und Versuche über die Ausscheidung der Harnsäure beim Menschen*, &c., Munich, 1858, S. 36—found that quinia produced considerable diminution in the quantity of uric acid eliminated; and this has been confirmed by KERNER—Jahrg. III, S. 97 *et seq.*, *op. cit.*, note *, *supra*—who has gone still further, and with great care measured in his own urine the variations in the quantity of the various nitrogenous excreta under the influence of quinia. His analyses took into account the urea, uric acid, creatinin, &c., separately as well as the total nitrogen-content of the urine. I must refer to his paper for details, but cite the following general results: Daily quantity of nitrogen excreted during the 1st, 2d and 3d days of the experiment, without quinia, 19.362 grammes; during the 4th, 5th and 6th days, still without quinia, 17.306 grammes; during the 7th, 8th and 9th days, under the influence of small repeated doses (.075 gramme eight times a day) of muriate of quinia, 16.170 grammes; during the 10th, 11th and 12th days, under the influence of a large dose (1 to 2.5 grammes) of muriate of quinia taken daily, 13.979 grammes. Then stopping the quinia during the 13th, 14th and 15th days, the mean daily excretion of nitrogen was 17.014 grammes, and during the 16th, 17th and 18th days, 19.070 grammes. The diet remained substantially uniform throughout the experiment. The greatest diminution in the nitrogen-excretion occurred on the 12th day, on which he took 2.5 grammes of quinia and passed only 12.73 grammes of nitrogen. ZUNTZ is stated by STRASSBURG—S. 343, *op. cit.*, *infra*—to have obtained on himself equally striking results. A comparison of three normal days with four under the influence of quinia in doses of 1.8 grammes showed a diminution of about 39 per cent. H. V. BOECK—*Untersuchungen über die Zersetzung des Eiweisses im Thierkörper unter dem Einflusse von Morphium, Chinin und arseniger Säure*, Munich, 1871, S. 31—experimented on dogs, and observed, under the influence of quinia, a greater diminution in the excretion of nitrogen than was produced by morphia: arsenic acid produced no such diminution. On the other hand, RABUTEAU—*Le sulfate de quinine ne diminue pas l'urée*, Comptes rendus de la Soc. de Biologie, T. V, 1868, p. 92—concluded, from experiments on himself and on dogs, that the elimination of urea is not diminished by quinia, although in the case of dogs the administration of arsenite of potassium was followed by a considerable diminution; and E. UNRUH—*Ueber die Stickstoffausscheidung bei fieberhaften Krankheiten*, Virchow's Archiv, Bd. XLVIII, 1869, S. 227—after ascertaining that in ileotyphus, erysipelas, pneu-

increase our confidence in the powers of the drug as a tonic and supporting remedy, but further investigations are needed.

Yet another point earnestly urged of late is the alleged power of quinia as an antiphlogistic. The observation of Binz, since often corroborated, that the addition of about one-four-thousandth part of this alkaloid to a drop of recently drawn blood inhibits the amœboid movements of the white corpuscles, led to a series of experiments by that observer and his disciples which seemed to show that by the administration of quinia the experimental development of inflammation could be prevented, and the course of inflammations previously excited beneficially modified. But contradictory observations have been brought forward by others, especially by Hayem, Bochefontaine and Köhler, who have succeeded in producing inflammation in frogs profoundly under the influence of quinia.* It cannot, therefore, be admitted that the antiphlogistic virtues ascribed to the drug have been fairly established by experimental evidence. Meanwhile it has been pretty freely administered in pneumonia and other internal inflammations, and with a certain degree of advantage, as indeed might have been expected from its power of diminishing febrile temperatures;† but no more by clinical observation than by experiment has it been demonstrated to exert any such antiphlogistic influence as would warrant its employment in the fluxes, unless it is indicated by other considerations than the mere existence of intestinal inflammation.

---

monia and other feverish diseases the total nitrogen-excretion was increased in the mean to about one-fifth more than the normal, (in a state of hunger,) found that the administration of sulphate of quinia sometimes diminished this result in a marked manner; but in other cases had no effect or was followed by an actual increase. In connection with the foregoing observations it must be mentioned that H. v. BŒCK und J. BAUER—*Ueber den Einfluss einiger Arzneimittel auf den Gasaustausch bei Thieren*, Zeitschrift für Biologie, Bd. X, 1874, S. 360—found that the action of quinia produced in man a little diminution in the amount of carbonic acid excreted by the lungs. Similar effects were produced on animals by small doses, but large doses produced convulsions, and then the carbonic-acid excretion was greatly increased. G. STRASSBURG—*Ueber die Ausscheidung der Kohlensäure nach Aufnahme von Chinin*, Archiv für experiment. Path. und Pharm., Bd. II, 1874, S. 341—experimented on rabbits, and found that in healthy animals quinia produced no diminution of the carbonic acid exhaled. In the case also of rabbits in which fever had been previously developed, it produced no marked effect. Taken altogether, the foregoing testimony seems to render it probable that one of the effects of quinia both in health and disease is to diminish tissue-metamorphosis, though further observations are needed to reconcile discrepancies. It is not, however, surprising that, as UNRUH'S observations show, the drug should sometimes fail to arrest the destructive processes in progress during grave febrile disorders. The following observations may stand related to the diminished tissue-metamorphosis possessed by quinia: When blood is allowed to putrefy out of the body it speedily diminishes in alkalescence in consequence of the formation of an acid, a process which has been studied especially by N. ZUNTZ—*Beiträge zur Physiologie des Blutes*, Inaug.-Diss., Bonn, 1868, S. 19 *et seq.* A. SCHULTE—*Ueber den Einfluss des Chinin auf einen Oxydationsprocess im Blute*, Bonner Inaug.-Diss.; I cite from the abstract in Centralblatt für die med. Wiss., Jahrg. IX, 1871, S. 727—found, as had previously been done by SCHARRENBROICH and ZUNTZ, that this process is hindered by quinia. Similar results have been obtained by BINZ—*Ueber Chinin und Blut*, Archiv für experiment. Path. und Pharm., Bd. I, 1873, S. 18—who regards it as indicating that quinia retards the process of oxidation in the blood. BINZ has also shown—*op. cit.*, S. 23 *et seq.*—that the addition of quinia interferes with the power of the blood to act as a carrier of ozone from ozonized oil of turpentine to tincture of the resin of guaiac or sulphate of indigo. He also observed that the blood of young cats that had received large but not fatal doses of quinia acted less than normal blood upon a tincture of guaiac.

* I refrain from a detailed discussion of this controversy. The following are the most important papers: C. BINZ—*Ueber die Einwirkung des Chinin auf Protoplasma-Bewegungen*, Archiv für mikroskop. Anat., Bd. III, 1867, S. 383; *Experimentelle Untersuchungen über das Wesen der Chininwirkung*. Berlin, 1868, S. 29; *Quinine and the colourless blood-corpuscles*, The Practitioner, Vol. IX, 1872, p. 141; as well as S. 137 *et seq.*, *op. cit.*, note *, last page. In support, more or less completely, of the view of BINZ, may be mentioned C. SCHARRENBROICH—*Das Chinin als Antiphlogisticum*, Inaug.-Diss., Bonn, 1867, and Berliner Klin. Wochenschrift, Jahrg. IX, 1872, S. 190; A. MARTIN—*Das Chinin als Antiphlogisticum*, Inaug.-Diss., Giessen, 1868; G. KERNER—*Ueber den Einfluss des krystallinischen und des amorphen Chinins auf die weissen Blutzellen und den Eiterbildungsprocess*, Pflüger's Archiv, Bd. VII, 1873, S. 122, and The Practitioner, Vol. X, 1873, p. 169; E. B. BAXTER—*The action of the cinchona alkaloids and some of their congeners on bacteria and colourless blood-corpuscles*, same Jour., Vol. XI, 1873, p. 321; and N. JERUSALIMSKY—S. 71, *op. cit.*, p. 800, *supra*. On the other hand, C. SCHWALBE—*Ueber die entzündungswidrige Wirkung des Chinin*, Deutsche Klinik, Bd. XX, 1868, S. 325—killed cats by the subcutaneous injection of poisonous doses of quinia, and, examining their blood immediately after death, was able still to recognize the amœboid movement, although only imperfectly, as he had no hot stage: (the experiments were performed in Costa Rica.) GELTOWSKY—*On the action of quinine on the colourless blood-corpuscles*, The Practitioner, Vol. VIII, 1872, p. 321—found that in the blood of frogs to which even a poisonous dose of quinia was administered subcutaneously, and of Guinea pigs into whose veins even a poisonous dose was injected, the amœboid movement continued unchecked. BOCHEFONTAINE—*Note sur quelques expériences relatives à l'action de la quinine sur les vibrioniens et sur les mouvements amiboïdes*, Archives de Physiologie, T. V, 1873, p. 389 *et seq.*—states—p. 731—that HAYEM in 1868 attempted in VULPIAN'S laboratory to repeat some of the experiments of BINZ. Two frogs were curarized; one of them was also intoxicated with chlorohydrate of quinia; the mesentery of each was drawn into the air, and the amœboid wandering of the leucocytes was equally observed in both BOCHEFONTAINE in 1873 repeated this experiment, with the modification that the mesentery was irritated with nitrate of silver, and obtained the same results. F. W. ZAHN—*Zur Lehre von der Entzündung und Eiterung*, Inaug.-Diss., Berne, 1871—came to the conclusion—S. 52—that the internal or subcutaneous administration of quinia hindered or diminished the migration of white corpuscles only when fatal disturbances of the circulation were first induced by it; and KÖHLER—*Ueber die Wirkungen des Chinin*, Bericht über die Sitzungen der naturforschenden Gesellschaft zu Halle im Jahre 1876, S. 22—who appears to have acted on this hint, on selecting from frogs in deep quinia narcosis those in whose webs the circulation appeared undisturbed, succeeded in developing in them inflammation of the mesentery, tongue or cornea, with abundant migration of white corpuscles. As for the observations of MANASSEÏN—*Ueber die Dimensionen der rothen Blutkörperchen unter verschiedenen Verhältnissen*, Berlin, 1872, which I have not been able to see, and cite from BINZ, S. 18, *op. cit.*, last note—that in fever the red blood corpuscles are diminished in size and regain their normal dimensions if the animal be brought under the influence of quinia, I must refrain from forming an opinion till I can read his paper, but meanwhile can see no connection between the phenomena, if correctly observed, and any of the therapeutic effects of the drug.

† See; in illustration, the papers of HAGENBACH and RAPMUND, as well as the report of the Committee of the Clinical Society, cited p. 800, *supra*.

Finally, and also under the leadership of Binz, considerable attention has been recently directed to the antiseptic influence of quinia. The belief, that by the administration of Peruvian bark it is possible to arrest the tendency to putridity of the humors in malignant fevers, was very general during the early part of the last century, and Pringle attempted to support it by a series of experiments published in 1750.* The speculation of Binz is merely a revival of this old view, which reappears with the support of an imposing parade of experiments conducted after modern methods. It is shown that a solution of quinia will retard or prevent the putrefaction of flesh, albumen, milk, urine and other organic substances. It is shown that this solution kills bacteria and other low forms of life, which are assumed to be the actual cause of the putrefactive process. It is still further assumed that the presence of certain varieties of these humble living forms in the blood is the cause of the so-called septic processes in disease, that quinia pursues them into the torrent of the circulation, kills them there, and thus cures.†

But much remains to be done before any one of these assumptions can be admitted to rest upon a solid basis of demonstration. Considerable difference of opinion exists even with regard to the comparatively simple question of the strength of the quinia solution necessary to kill bacteria out of the body. Calculating from the proportion he found necessary to kill the bacteria of putrid blood, Bochefontaine asserts that, if forms of similar vitality in the circulating blood are imagined to be the cause of septic fevers, it would be necessary to introduce no less than seventeen grammes of the chlorohydrate of quinia into the blood of an adult to kill them; and the same observer has found that in living frogs intoxicated with quinia it is quite as easy to cause the development of bacteria in the blood (bactérihémie) as in those to which no quinia has been given.‡

Meanwhile, during the progress of the controversy on this doubtful point, there have not been wanting those who have regarded the antiseptic virtues of quinia as at least sufficiently probable to warrant a renewed trial of its efficacy in pyæmia and other septic

* These experiments are contained in a series of papers entitled *Experiments and observations upon septic and antiseptic substances*, read to the Royal Society during the year 1750, Philosophical Trans. abridged, Vol. X, 1756, p. 1365: they are reprinted in full in the first edition of his *Obs. on the Dis. of the Army*, London, 1752, and all subsequent editions. He found that pieces of meat immersed in a strong infusion of chamomile flowers, Virginia snakeroot or Peruvian bark did not putrefy under conditions which were attended by rapid putrefaction if they were immersed in simple water—Exp. viii, p. 374, and Exp. xi, p. 378. Indeed, pepper, ginger, saffron, galls, mint, green tea, red roses and several other vegetable substances seemed to produce a similar antiseptic effect. I note that he thought this power of the bark "perhaps less than of the snake-root or chamemile flowers." In Exp. xiii, p. 381, he was "able to sweeten several small pieces of putrid flesh, by repeated affusions of a strong decoction of the bark;" and "constantly observed, that not only the corrupted smell was removed, but a firmness restored to the fibres." He boldly applied these observations to the interpretation of the operation of Peruvian bark in disease: "Now, since the bark parted with so much of its virtue in water, it was natural to think it would still yield more in the body, when opened by the saliva and bile; and therefore, that it was by this antiseptic virtue it chiefly operated. From this principle we might account for its success in gangrenes, and in the low state of malignant fevers, when the humours are so evidently putrid. And for intermitting fevers, in which the bark is most specific, were we to judge of their nature from circumstances attending them in climates and seasons most liable to the distemper, we should assign putrefaction as a principal cause."

† BINZ: see his memoirs cited in note *, p. 802, *supra*, also *Weitere Studien über Chinin*, Berliner klin. Wochenschrift, Jahrg. VIII, 1871, S. 564 *et seq.*; also the memoir of E. B. BAXTER, cited in the same note. BAXTER experimented also, as BINZ had previously done, (Virchow's Archiv, Bd. XLVI, 1869, S. 129,) with other alkaloids of bark and with the sulphate of beberia. He concludes that quinia and quinidine possess equal antiseptic power; "next comes cinchonidine; last, though at no great distance, cinchonia"—p. 343, *op. cit.*—and that sulphate of beberia approaches and rivals the cinchona alkaloids in antiseptic power—p. 335.

‡ BOCHEFONTAINE—*op. cit.*, note *, last page—arrived at quite different results from those reported by BINZ as to the strength of the quinia solution necessary to kill bacteria and vibrios. For the estimate in the text, see p. 405, *op. cit.* Furthermore, he dropped three or four drops of fresh blood into a solution of one part of chlorohydrate of quinia to 1,000 parts of water, and observed that bacteria were developed by the end of forty-eight hours. In four or five days the solution contained "populations of bacteria, vibrios and spirilla." Finally he made use of an experiment of VULPIAN to develop bacteria in the blood of living frogs, (bactérihémie.) If a small quantity of cyclamine (the active principle of the root of cyclamen Europæum, see U. S. Dispensatory, 12th Ed., 1865, p. 1508) be introduced beneath the skin of a frog, a local inflammatory (septic) process is developed, bacteria form in the blood in great numbers, and death ensues in a few days. Now a drop of a solution containing $\frac{1}{10000}$th part of the blood of such a frog will transmit the bacterian infection of the blood (bactérihémie) to healthy frogs, or, as BOCHEFONTAINE found also, to frogs intoxicated with quinia. He found further that the administration of intoxicating doses of quinia to bacterihemic frogs in no wise affected the bacteria. He concluded, therefore: "Chez les grenouilles en état de bactérihémie, l'intoxication par la quinine ne détruit pas les bactéries ou les vibrions;" and that, "La bactérihémie expérimentale paraît se développer également chez les grenouilles intoxiquées par la quinine et chez les grenouilles qui ne le sont pas"—p. 733. For an account of the mode of experimenting with cyclamine, referred to in this note, see A. VULPIAN—*Développement de vibrions pendant la vie, dans le sang des grenouilles empoisonnées par la cyclamine.—Intoxication de grenouilles saines par inoculation du sang des grenouilles ainsi empoisonnées*, Archives de Physiologie, T. I, 1868, p. 466.

diseases;* I say a renewed trial, for its use in these affections is no new thing. But its other better established powers are sufficient to account for the degree of success which has long attended it, and these recent trials, like the older ones, have failed quite often enough to discredit the speculation that the drug acts as a parasiticide capable of slaying the living cause of the disease. In like manner some of those who believe that bacteria cause the fluxes have brought it into use as an antiseptic in these diseases also.† The experiments which have been published are as yet too few to warrant any very positive conclusions, but I confess I see no reason to anticipate ultimate success in this direction.‡

It is not necessary to say much here in regard to the proper doses of quinia, the subject being now in most quarters well understood. Broken doses amounting to from three to ten grains daily are generally sufficient when the tonic or supporting influence of the drug is desired; but when the object is to lower the temperature in febrile conditions, or to cut short the progress of malarial fevers, from twenty to thirty grains given in a single dose, or at least within an hour, are usually required, and in severe cases a still larger quantity, forty to sixty grains, is often necessary. These large doses had been previously employed by a few physicians, as Bally (1830) in France, Fearn (1836) and May (1837) in the southern United States;§ but it was chiefly in consequence of the successful experience of the medical officers of the United States Army,‖ who used it on a large scale during the Florida

* See, for example, the discussion on the address of P. G. HEWETT—*On pyæmia in private practice*, Trans. of the Clinical Society of London, Vol. VII, 1874, p. li *et seq.*, and The Lancet, 1874, Vol. I, p. 337 *et seq.*—especially the statements of DURHAM—p. xcv *et seq.*—as to the effects of quinia, in half-drachm doses repeated every three or four hours, observed by himself in hospital practice, and those of GORDON—p. cii *et seq.*—as to his observations of the practice of the French surgeons during the siege of Paris. He tells us that "There were several kinds of treatment employed. One was—and I believe it is that which was adopted most frequently—the administration of very large doses of quinine;" and also, "that the recoveries are recorded as being not by any means unfrequent"—p. civ.

† Thus, for example, WM. JOHNSTON—*Summer diarrhœa: its nature, cause, and treatment*, The Lancet, 1878, Vol. II, pp. 397 and 433—has arrived at the conclusions that "(a) diarrhœa, as it affects both adults and infants during the summer months, owes its origin, in the great majority of instances, to the introduction of minute living organisms (bacteria) into the system by means of air or in food; and (b) the disease depends upon putrefactive changes in the bowel contents, which changes are correlative to the development and multiplication of these microscopical organisms." Of course he thinks the treatment should consist in giving antiseptics, such as "carbolic acid, quinine, salicylic acid, the mineral acids (especially the dilute sulphuric), thymol, benzoic acid, and borax"—p. 434.

‡ It is not necessary to the purpose here in view to discuss the imperfect observations hitherto made with regard to the influence of quinia upon the nervous system. The following are the most important papers: A. EULENBURG und T. SIMON—*Ueber die Wirkungen des schwefelsauren Chinins auf das Nervensystem*, Berliner klin. Wochenschrift, Jahrg. I, 1864, S. 48, and Archiv für Anat. Physiolog. und wiss. Med., Jahrg. 1865, S. 423; T. A. CHÁPERON—*Beitrag zur Kenntniss der physiologischen Wirkung des Chinin*, Inaug.-Diss., Wurzburg, 1869; H. HEUBACH—*Einwirkungen des Chinins auf das Nervensystem*, Centralblatt für die med. Wiss., Jahrg. XII, 1874, S. 673; and *Beiträge zur Pharmakodynamik des Chinins*, Archiv für experiment. Path. u. Pharm., Bd. V, 1876, S. 1; C. v. SCHROFF, jun.—*Beitrag zur Kenntniss der Chininwirkung*, Stricker's Med. Jahrb., Jahrg. 1875, S. 175. I think it must be admitted, as stated by BUCHHEIM—S. 436, *op. cit.*, p. 746, *supra*—that the effects of medicinal doses upon the nervous system are not clearly made out. As for the speculation of H. BENCE JONES—*Lectures on some of the applications of chemistry and mechanics to pathology and therapeutics*, London, 1867, p. 28 *et seq.*—that quinia acts by replacing a fluorescent substance normally contained in the blood and other fluids of the body, which is deficient in malarial fevers, &c., I attach no particular importance to it in the present state of our knowledge. The reader may consult on this subject the corroborative observations of E. RHOADS and W. PEPPER—*A contribution toward our knowledge of the pathological changes in the fluorescence of the tissues*, Pennsylvania Hospital Reports, Vol. I, 1868, p. 269; and the abstract of the observations of CHALVET—*Note sur la prétendue quinoïdine animale de Bence Jones*, Gaz. Hebdom., T. V, 1868, p. 289—which seem to show that the so-called normal fluorescence is dependent upon the ingestion of fluorescent vegetable matters present in a variety of articles of diet.

§ BALLY—*Du sulfate de quinine à haute dose*, La Lancette Française, T. IV, 1830, p. 91—gave it with success at the Hôtel-Dieu to cases of intermittent fevers in the dose of 30, 40 and even 60 grains. THOMAS FEARN—*On sulphate of quinine in large doses*, The Transylvania Jour. of Med., Lexington, Ky., Vol. IX, 1836, p. 705—states that he had been in the habit of giving in remittent fever three doses of twenty grains each with an interval of an hour between, and reports a case in which 96 grains were given successfully: the patient became temporarily "almost blind." Indeed, this author mentions that "in two or three instances blindness, or obscurity or confusion of vision" occurred temporarily after his usual doses. J. E. MAY—*On the remedial use of sulphate of quinine in large doses*, same Jour., Vol. X, 1837, p. 217—relates FEARN'S case and several others, and thinks the dose "should be regulated by the strength, or vital energy of the patient. If there be much prostration and torpor of the general system, mammoth doses."

‖ An account of this interesting question will be found in the first *Statistical Report* of COOLIDGE—p. 637, *op. cit.*, p. 416, *supra*—who has collected and republished the original official documents relating to it. He prudently writes: "Without attempting to decide upon the *originality* of this practice, in *any of its phases*, or to determine to whom, among the medical officers, is due the merit of introducing it into the army, (for on this point the official records are silent,) it may with truth be said, that to the medical staff of the army belongs the credit of having demonstrated, on an extensive scale, its safety and efficacy, and of having thereby largely contributed to revolutionize the treatment of fever in this country. It has not been practicable to ascertain from the official records the *precise time* of the introduction into the army of the practice of giving quinine in large doses. The earliest reports of sick, in which that practice is alluded to, refer to the treatment as having been adopted some time previously. The reports of Assistant Surgeon (now Surgeon) J. J. B. Wright, for the quarter ending June 30, 1841, and of Assistant Surgeon (now Surgeon) Charles McCormick, for the quarter ending September 30, 1841, are the first which are accompanied with any special or detailed account of this treatment." To which I may add that Surgeon WRIGHT expressly states that he adopted the plan in 1841 at the suggestion of Surgeons B. F. HARNEY and B. RANDALL. And from the reports of these officers it appears that HARNEY first employed them in 1838—see p. 648—and RANDALL in 1840—see p. 649. MCCORMICK is ambiguous on this head, but in his report, dated October 11, 1841—see p. 638—he states that two years previously he abandoned quinia on account of its inefficiency in ordinary doses, and commenced using the large doses at some unspecified subsequent period.

war, that the safety and efficiency of the method was established. When it is desired to combine the tonic action of quinia with the effect of iron upon the blood the *citrate of quinia and iron* is an eligible preparation, which was employed on a large scale with good results during the civil war;* five to ten grains may be given three times daily.

As for the other alkaloids of Peruvian bark, especially *cinchonia*, it has generally been held that their action, although feebler, is essentially similar to that of quinia.† A large quantity of sulphate of cinchonia was issued during the civil war and used as a substitute for quinia.‡ Some of the medical officers with whom I have conversed state that it often irritated the stomach and caused headache, and all regarded it as less efficacious than quinia; but I heard no such complaints as might have been anticipated, were it true, as has recently been advanced by Dupuis and Laborde, that cinchonia and cinchonidia are endowed with poisonous properties, and exhibit such a tendency to produce convulsions as should exclude their therapeutic use;§ yet the experiments by which this conclusion is supported appear to have been made with care, so that further inquiry is exceedingly desirable.

In this place allusion may also be made to the *bark of the willow*, (salix alba,) which was brought into use in dysentery during the latter part of the last century by Van Geuns, who regarded it as possessed of antiseptic virtues superior even to those of Peruvian bark.‖ Its active principle, *salicin*, after pretty generally recognized failure as a substitute for quinia,¶ has recently been essayed as a remedy for diarrhœa by Lawson and others.** Undoubtedly it possesses tonic properties, but it may well be questioned whether it is really more useful in the fluxes than the other vegetable bitters.

More considerable importance attaches to the employment of *nux vomica* and its alkaloid *strychnia*.†† Nux vomica was first used for the treatment of dysentery in the

---

* See note †, p. 800, *supra*, for a statement of the quantity purchased.

† These alkaloids are quinidia, cinchonia and cinchonidia. For an account of them, with references to the literature previous to 1871, I refer the reader especially to the work of the HUSEMANNS—S. 324 *et seq.*, *op. cit.*, p. 766, *supra*. In view of the great cost of quinia, the East India government instituted in 1866 an experimental inquiry into the comparative value of these alkaloids in paroxysmal fevers. These inquiries were made in Bombay and Bengal as well as in Madras, but, so far as I can learn, only the latter were published. I have not been able to see the *Report of the Madras Chinchona Commission*, as printed in Parliamentary Blue Book, No. 432, East India, but find a copy of it in the *Proceedings of Government, Revenue Department*, 18th April 1868, published by the Madras Quarterly Jour. of Med. Sci., 2d Series, Vol. I, 1868-9, p. 192 *et seq.* The Commission conclude: "That ordinary sulphate of quinine, chemically pure sulphate of quinine, and sulphate of quinidine possess equal febrifuge power; that sulphate of chinchonidine is only slightly less efficacious; and that sulphate of chinchonine, though considerably inferior to the other alkaloids, is notwithstanding a valuable remedial agent in fever"—p. 198. An abstract of this report will be found in The Lancet—*The sulphates of the new chinchona alkaloids as substitutes for quinine*—1873, Vol. I, p. 747. See also J. EWART—*Report on the therapeutical value of the cinchona alkaloids*, &c., The Indian Annals of Med. Sci., Vol. XIII, 1869, p. 1—who arrives at substantially the same conclusion, with the additional observation as to cinchonia, that "the irritability of stomach set up by it is *the* great objection to its ever taking rank as a substitute for either of the preceding alkaloids." Compare the abstract of the thesis of J. DOUGALL—*The febrifuge properties of the cinchona alkaloids*, Edinburgh Med. Jour., Vol. XIX, Part I, 1873, p. 193—who comes to the same general conclusions, and adds that quinia requires only from two-thirds to three-quarters the dose to produce the effects of a given quantity of quinidia, the most active of the three baser alkaloids. It is interesting to note how closely the observations of BAXTER—p. 343, *op. cit.*, p. 802, *supra*—on the relative antiseptic power of these alkaloids, agree with the previously announced conclusions of the Cinchona Commission.

‡ See note †, p. 800, *supra*, for a statement of the quantity purchased for issue.

§ DUPUIS et LABORDE—*Étude expérimentale des succédanés de la quinine*, La Tribune Méd., 11me année, 1878, p. 147 *et seq.* These gentlemen found that subcutaneous injections of 75 centigrammes of sulphate or muriate of cinchonia produced epileptiform convulsions in vigorous dogs; cinchonidia produced similar effects. They conclude in forcible language: "Ces substances appartiennent plutôt à la catégorie des substances toxiques que des substances médicamenteuses, et que, par conséquent, la toxicologie les réclame plutôt que la thérapeutique"—p. 210. In this connection I may refer to a statement in New Remedies—*The relative values of cinchonidia and quinia*—September, 1876, p. 271, that the Medical Board of Bellevue Hospital have caused experiments to be instituted as to the use of cinchonidia sulphate, and that while the surgical members found it entirely unsuitable for surgical cases, on account of its tendency to excite emesis, the board regarded it, apparently, as good enough for "purely medical affections."

‖ VAN GEUNS—§ 14, S. 52, *op. cit.*, p. 649. *supra*—indeed appears to have regarded the willow bark as an antiseptic, "ein Fäulnisswidriges Mittel in der Ruhr." He gave it in decoction; see formula 15, S. 365, *op. cit.*

¶ See the article on salicin in the work of the HUSEMANNS—S. 959, *op. cit.*, p. 766, *supra*—for references to the literature of this subject.

** LAWSON—*op. cit.*, note *, p. 773, *supra*—advised the use of 6 to 8 grains of salicin once to thrice daily in cases of summer diarrhœa resulting from the direct action of heat on the nervous system. See also J. B. MATTISON—*The value of salicin in obstinate diarrhœa*, The Med. and Surg. Reporter, Vol. XXVIII, 1873, p. 107—who divides a drachm of salicin into 24 pills, and gives to adults two every four hours; J. C. BISHOP—*Salicine in diarrhœa and dysentery*, The Southern Med. Record, Vol. IV, 1874, p. 585; also *Comparative value of opium and salicine in diarrhœa and dysentery*, Detroit Review of Med. and Pharm., Vol. X, 1875, p. 387; and J. K. SPENDER—*Remedies for chronic diarrhœa*, The British Med. Jour., 1876, Vol. II, p. 750.

†† Nux vomica was unknown to the Greek physicians, and a difference of opinion exists as to whether the Arabians were acquainted with it. ADAMS, in his remarks *On the substances introduced into the materia medica by the Arabians*, appended to Book VII, Sect. III, of his version of PAULUS ÆGINETA, Vol. III, p. 461, *op. cit.*, p. 624, *supra*, argues in favor of the view that the substance, which in the mediæval Latin versions of RHAZES, HALY ABBAS and SERAPION is called nux vomica, and SONTHEIMER in his version of EBN BAITHAR translates strychnos nux vomica, is identical with our

Linköping epidemic, (1772,) by the Swedish physician Hagström. Accepting Nyander's speculation that dysentery is caused by acaridæ, he gave it in scruple doses as a parasiticide, expecting that its well known poisonous effects upon quadrupeds would be readily exerted upon these minute creatures.* The attention of Hufeland was directed to the drug by these observations, and he used it freely, with alleged success, in the Jena epidemic of 1795; but he explained the effects of his treatment by different, though equally erroneous, speculative considerations. He started out with the belief that nux vomica is one of the most powerful narcotic and antispasmodic substances at the disposal of the physician;† and, as so often happens, his great clinical experience only served to strengthen his confidence in this mistaken view. How such an error arose is only too painfully clear to the intelligent medical historian. The European Arabists had confounded the nux methel of the Arabians with nux vomica, and subsequent writers, by a literary error, attributed the narcotic properties of the former to the latter. Copied from one book on therapeutics to another without the check of scientific experiment,‡ it is not strange that Hufeland commenced his trial of

modern nux vomica. RHAZES—*Ad Manzor de re med.*, Lib. VIII, Cap. 49, p. 205, Ed. cited p. 678, *supra*—classes nux vomica with white hellebore and other emetics, and tells what to do if syncope or spasms follow the ingestion of excessive doses. HALY ABBAS—*Practica*, Lib. II, Cap. 55, fol. 182, also Lib. X, Cap. 12, fol. 304, Ed. cited p. 678, *supra*, and SERAPION—*Practica*, Tract. VII, Cap. 36, fol. 112, and *De temp. simp.*, Cap. 163, fol. 145, Venetiis, apud Juntas, 1550—speak of its medicinal use as an emetic; the latter author calls it "Lenm alkei, vel alke, id est nux vomica." EBN BAITHAR—Bd. I, S. 270, Ed. cited p. 704, *supra*—calls it Dschawz elkai, which SONTHEIMER translates strychnos nux vomica. He cites several Arabian authorities for its medicinal use as an emetic in two-drachm doses, the dose mentioned by SERAPION, and states that it has been found useful in paralysis and trismus. According to AINSLIE—*Mat. Indica*, London, 1826, Vol. I, p. 319—the tree is a native of Persia, so that it is probable enough the Arabian physicians were acquainted with it. Yet, according to DALE—p. 328, *op. cit.*, p. 729, *supra*—the nux vomica of SERAPION is St. Ignatius bean, (the bean of strychnos Ignatii,) and PEREIRA—Vol. II, p. 533, Ed. cited p. 746, *supra*—adopts this view, suggesting that "it is probable that the nux-mechil of Serapion is the substance which we denominate nux-vomica:" compare SERAPION—*De temp. simp.*, Cap. 164, fol. 145, *op. cit.* The nux methel which AVICENNA—Lib. II, Tract. 2, Cap. 568, Ed. cited p. 632, *supra*—describes as resembling the nux vomica, has also been supposed to be our nux vomica: see note ‡, *infra*. But AVICENNA not merely speaks of it as poisonous, but as stupefying; and elsewhere—Lib. IV, Fen. 6, Tract. 1, Summa 3, Cap. 2, Vol. II, p. 206, *op. cit.*—declares that it produces vertigo, redness of the eyes, intoxication and profound sleep. It is more probable that the nux methel was the fruit of a species of datura: see ADAMS—*loc. cit.* Both STILLÉ—Vol. II, p. 177, *op. cit.*, p. 711, *supra*—and the authors of the *Pharmacographia*—p. 384. *op. cit.*, p. 704, *supra*—express doubts as to whether any of the Arabian passages cited above really refer to our nux vomica. STILLÉ objects that the effects ascribed by the Arabians to their nux vomica are quite different from those actually belonging to that substance: "It is stated to be emetic and purgative, and its dose is given as two drachms; but no allusion is made to its possessing poisonous properties." How, then, about the poisonous properties described by RHAZES—*supra?* And is it really an objection that the Arabians regarded it as an emetic? so did DALE—see note ‡, *infra*—but we know that he had our nux vomica. GESNER and FALLOPPIUS were sure that it was a sudorific; HUFELAND was sure that it was not, but held it, as GESNER, DALE and others had done before him, to be a narcotic—see note ‡, *infra*. Is it possible to conclude anything more from these conflicting views than the uncertain character of clinical experience? Nevertheless, I readily admit that the identity of the Arabian drug is by no means positively established by the testimony in our possession.

* J. O. HAGSTRÖM—*Rön, Om Nucis Vomicæ nytta emot Röd-sot*, Kongl. Vetenskaps Academiens Handlinger, Vol. XXXIV, 1773, p. 301—was sent as commissioner to investigate the epidemic referred to, and succeeded beyond his most sanguine expectations with nux vomica; so much so that, being unable to remain in the afflicted districts, he left behind him, on his return, with clergymen and other prominent persons, considerable quantities of the drug, and in view of the popular prejudice against nux vomica as a poison (how unreasonable these prejudices!) endeavored to secure its more general use by calling it the "American powder," and, afterwards, "sedative powder." J. L. ODHELIUS—*Rön, Om Lepra*, same Trans., Vol. XXXV, 1774, p. 266—who is cited by HUFELAND (see next note) as testifying also to the success of nux vomica, appears only to have given it in one case, in which, a long lumbricoid having been passed, he gave the nux in 15-grain doses, twice daily; the patient died, but of course he explains this was from her own neglect of diet, &c.; otherwise so excellent a medicine would certainly have cured her.

† HUFELAND—S. 108, *op. cit.*, p. 740, *supra:* "Es war mir diess Mittel aus Hagströms Erfahrungen bekannt, der es schon so glücklich gegen die Ruhr gebrauchte. Ich wuste, dass es eines der stärksten krampfstillenden und narcotischen Mittel ist, die wir besitzen," &c.

‡ I cannot better illustrate the manner in which nux methel and nux vomica were confused than by citing the following passage from FALLOPPIUS—*De tumoribus præter naturam*, Cap. XXVII, *De bubone pestifero*, Opera, Frankfort, 1600, T. I, p. 670: "Germani secta vena (secant enim quandoque) exhibent nucem vomicam, seu medicamentum nucis vomicæ. Notandum, quod nux vomica officinarum est nux methel, nux vero officinarum methel est nux vomica Arabum, qua nuce utimur ad interficiendum canes, et hac utuntur Germani in pestiferis buboníbus, et loquutus sum cum scholaribus Germanis, qui assumserunt hujus nucis scrup. unum, aut scrup. dues, et quandoque usque ad drach. unam. Symptoma quod succedit, est sudor magnus, quibus vero hic sudor accidit, evadunt. Verum ego hanc nucem non exhiberem: quoniam est medicamentum venenosum, et mortiferum." As is well known, this treatise was published posthumously, and the versions differ considerably. Thus, in the Venice edition of the Opera, 1606, T. III, fol. 68, where substantially the same story is told, the dose is not given, and FALLOPPIUS is made to speak less positively against the use of the drug; for although he remarks "apud me est suspectum," yet he concludes, "quare possetis, et vos exhibere tale medicamentum: nam licet vomica nux sit venenum canum, fortasse erit antidotum respectu hominum: nam multa reperiuntur, quæ sunt venenum uni speciei animalium; alteri vero antidotum." All which is true, no doubt; but, alas, we know too well now that the nux in proper doses kills men as readily as dogs! CONRAD GESNER—*Epist. Med.*, Lib. III, fol. 114, Ed. cited p. 752, *supra*—in an epistle written in 1565, three years after the death of FALLOPPIUS, had classed nux vomica, with opium and solanum somniferum, among the substances which provoke sweat, and are therefore useful in the plague, (contra pestem;) and in 1564—Lib. I, fol. 33—he wrote to ACHILLES P. GASSER that he now certainly knows that nux vomica is narcotic, (nucem vomicam narcoticam esse,) which hitherto he had doubted, for having given half a scruple to a dog, after half an hour it slept, and died within four hours, and that sometimes its head, sometimes its legs were convulsed during sleep. DALE—p. 327, *op. cit.*, p. 729, *supra*—gives nux metella among the synonyms of nux vomica, and writes of its medical properties: "Narcotica est, virulenta, et opio deterior. Canes, feles, corvos, &c. cum cibo exhibita interimit, vomitumque ciet." MANGETUS—T. II, p. 448, *op. cit.*, p. 736, *supra*—who describes the drug under the head of nux metella, adopts the above citation from DALE, except the remark about vomiting, as to which he says: "Nux vomica perperam vocatur hic fructus cum vomitum non moveat;" and doubts its identity with the nux methel of the Arabians: "Nucem metel Arabum nonnulli cum nuce vomica eandem esse, volunt, verum descriptiones ei non conveniunt." JAMES—Art. *Nux vomica*, T. III, *op. cit.*, p. 690, *supra*—borrows his account chiefly from DALE and MANGETUS; he repeats: "The nux vomica is narcotic, virulent, and even worse than opium." ALSTON—Vol. II, p. 39, *op. cit.*, p.

nux vomica with this belief; but experience with considerable doses, eighteen to thirty grains of the powder, ten to twelve of the extract, daily, did not disabuse his mind in spite of the occasional development of characteristic toxic symptoms in his patients.*

The statements of Hufeland induced others to make trial of nux vomica in dysentery. Berends, Richter, P. L. Müller and Vaux employed it with alleged success; but Hargens in the Kiel epidemic (1798) was much less fortunate, and Schmidtmann in the Melle epidemic (1800) was so unsuccessful that he subsequently ceased to use it, while Rademacher and Horn, although they regarded it as beneficial, were led to administer it usually in combination with opium.† Naumann, in discussing the question, called attention to the poisonous effects of large doses, and counselled caution in the use of the drug; yet even he attributed to it a narcotic power, although he admitted this was not very decided.‡ Hauff tried it in a few cases without success during the Wurtemburg epidemic of 1834, and returned to opium as a more efficient and safer remedy.§ Meanwhile nux vomica had been employed with more or less advantage in certain chronic fluxes by Bucholz, Hufeland, Rummel, Récamier and Frisch;‖ and *strychnia*, first isolated in 1818, had been brought into use in similar cases by Graves (1827) and Bardsley, (1830.)¶

772, *supra*—cites MILLER as saying, "I know of no physical use these nuts are applied to, they being narcotic and poisonous, and only used to destroy cats, dogs, etc." Both he and JAMES regarded them as unfit for medicinal use. HUFELAND may, therefore, well be excused for having imbibed the idea that nux vomica is narcotic; and yet more than a century before he wrote, LOSS—*Diss. de nuce vomica*, Wittenberg, 1683; which I have not been able to see, and quote from MURRAY—T. I, p. 479, *op. cit.*, p. 752, *supra*—from an analysis of the symptoms of poisoned animals, had arrived at the just conclusion that the drug was not truly a narcotic: "Sic igitur verum somnum, instar narcoticorum, non movet, sed insensilitatem sive stuporem." See also the references in MANGETUS, JAMES, ALSTON and MURRAY to the early observations of the symptoms of poisoning by nux vomica in animals and even in man. I may conclude this note by expressing my surprise that so recent a writer as BAMBERGER—S. 417, *op. cit.*, p. 578, *supra*—should still speak of nux vomica as a narcotic: "Von den übrigen Narcoticis ist besonders die Nux Vomica öfters angewendet worden." VOGT—S. 204, *op. cit.*, p. 645, *supra*—on the other hand, wisely remarks: "Es ist * * * aber durchaus kein Narcoticum in gewöhnlichen Sinne."

* HUFELAND—*op. cit.*, note †, last page. Note the symptoms described on S. 125. A woman took six grains of the extract, and six hours later three more: "Sie bekam hierauf eine ausnehmende Schwäche der Glieder, dass sie sich nicht auf den Beinen halten konnte, allgemeines Zittern, Schwindel, Betäubung des Kopfs, Aengstlichkeit, und einen kleinen aussezenden Puls." Such symptoms must have been far from uncommon in his experience, for he boasts: "Ich weiss Personen, die binnen 24 Stunden 10 ja 12 Gran [of the extract] in getheilten Dosen verzehrten, ehe sie Schwindelanfälle bemerkten"—S. 128. And yet with all this experience he could write: "Die Hauptkraft dieses Mittels ist die narcotische; es nimmt eben so schnell Schmerzen und Krämpfe weg, als Opium und die besten andern Narcotica"—S. 124. I note also as interesting that, contrary to GESNER and FALLOPPIUS, he did not think nux vomica sudorific, and substituted or combined opium when he wished to act upon the skin—S. 127.

† BERENDS, as cited by NAUMANN—Bd. IV, Abth. 2, S. 88, *op. cit.*, p. 645, *supra;* RICHTER—Bd. II, (1821,) S. 133, *op. cit.*, p. 777, *supra;* P. L. MÜLLER—*Med.-chir. Beob.*, Hufeland's Jour., Supplement—Stück des Jahrg. 1825, S. 39, and Neue Jahrb. der teutschen Med. u. Chir., Bd. XII, St. 3, 1826, S. 28; G. VAUX of Ipswich, is stated by J. ARMSTRONG—*Lectures on acute and chronic diseases*, (1834;) I cite the Amer. Ed., Philadelphia, 1837, p. 338—to have employed nux vomica with great success in dysentery during sixteen years, and in about two hundred cases: "It neither purges nor constipates, but removes the inflammation, and healthy evacuations follow." HARGENS—S. 134, *op. cit.*, p. 770, *supra*—expresses his disappointment with its effects, in most of the acute cases in which he tried it, in decided terms. It even seemed sometimes to increase the tormina; yet it was occasionally serviceable in cases in which opium was not well borne, and in the later stages of the disease when it began to assume the characters of lientery. L. J. SCHMIDTMANN—*Summa Obs. Med.*, Berlin, Vol. I, 1819, p. 201—states that it did not respond to his expectations, although "conscious that the intestines of the Westphalians are endowed with a less degree of sensibility than those of the Saxons," he augmented the dose to 2 or 2½ grains of the extract every two hours; it seemed to control the tormina, but often increased the tenesmus. In subsequent years, therefore—p. 202, note—he relied instead on opium, which never deceived him. RADEMACHER—p. 210 *et seq.*, *op. cit.*, p. 734, *supra*—tried nux vomica in dysentery, as SCHMIDTMANN had done, on the authority of HUFELAND. He evidently hesitated to use it, for he wrote: "Ut vero difficile est insuetis armis pugnare, ita molestum, novum adhibere pharmacum, præsertim cum morbus est periculosus." He came, however, after some trial, to the conclusion that it was a useful remedy; but fifteen grains of the extract did not suffice to check the dysenteric discharges sufficiently, and therefore he added to this quantity fifteen drops of the tincture of opium. This combination speedily cured all the cases on which he tried it: "Hoc modo omnes meam opem implorantes paucis diebus sanavi"—p. 215. E. HORN—*Etwas über die diesjährige Ruhr*, Horn's Archiv, Bd. II, Jahrg. 1811, S. 245: "Auch in diesem Herbste sind die wiederholten Versuche über die Wirksamkeit der Krähenaugen günstig ausgefallen, auch diesmal hat es sich gezeigt, dass die Verbindung dieses Mittels mit Opium in einigen Fällen entschieden nützte, wo das Opium allein, selbst in grössern Gaben angewandt, den krankhaften Zustand nicht merklich weiter zu bringen schien."

‡ NAUMANN—*loc. cit.*, last note: "Nach grösseren Gaben derselben hat man starken Ekel, mit Schwindel und heftigem Durst, Erbrechen, Verstopfung, oder reichliche blutige Ausleerungen, zuletzt Convulsionen und Lähmung beobachtet; indessen besitzen sie eigentlich narkotisirende Wirkungen nur in geringem Grade." He thought it should only be tried in the later stages of dysentery, and that perhaps it might be especially suitable in epidemics complicated with intermittent fever.

§ HAUFF—S. 412, *op. cit.*, p. 534, *supra.*

‖ BUCHOLZ, cited by HUFELAND—S. 109, *op. cit.*, note †, last page—who mentions that he himself had done the same. L. RUMMEL—*Der Fluxus cœliacus oder die Milchruhr*, Hufeland's Jour., Bd. LX, St. 6, 1825, S. 33. RÉCAMIER, as cited by A. RICHARD—*Élémens d'Hist. Nat. Méd.*, Paris, 1831, T. II, p. 148. FRISCH, as cited by A. T. THOMSON—*Elements of Mat. Med. and Ther.;* I quote from the 2d Ed., London, 1835, p. 192.

¶ PELLETIER et CAVENTOU—*Mémoire sur un nouvel alcali végétal (la strychnine) trouvé dans la fève de Saint-Ignace, la noix vomique*, &c., Annales de Chim. et de Phys., T. X, 1819, p. 142. R. J. GRAVES—*Clinical observations*, Dublin Hospital Reports, Vol. IV, 1827, p. 49. He used it on the strength of RUMMEL'S experience with extract of nux vomica, in the dose of $\frac{1}{12}$th of a grain twice daily, in a case of "whitish stools" following dysentery; the patient recovered in about three weeks. This case is referred to in his *Clinical lectures*, Vol. II, p. 218, Ed. cited p. 778, *supra.* J. L. BARDSLEY—*Hospital facts and obs.*, London, 1830, p. 42 *et seq.*—reports six cases of chronic diarrhœa successfully treated with $\frac{1}{8}$th of a grain of strychnia twice or thrice daily. He remarks: "I do not consider the strychnia a suitable remedy in those instances of diarrhœa, which depend upon an evident inflammatory condition of the mucous membrane of the intestines, but I more particularly recommend it in cases of a *chronic kind*, occurring in persons somewhat advanced in life, and of feeble constitution"—p. 49.

In 1834, Geddings of Baltimore, Maryland, revived the method of Vaux, and used strychnia also in the treatment of dysentery; he employed these remedies especially in cases verging upon a chronic form, and with alleged success.* Cornell, in 1849, during a local outbreak of dysentery, resorted to the same measures, but did not hesitate to use them during the acute stage.† Both these physicians were led by their observations to prefer the powdered nux vomica to strychnia. During the last twenty years, however, neither of these substances has been prescribed to any extent in the acute stages of dysentery, though their employment in the later periods of the disease and in the chronic fluxes has continued to find favor. Some have preferred the powdered nux vomica or its alcoholic extract for this purpose;‡ but these more bulky and less certain preparations have been very generally replaced by strychnia in recent practice.§

During our civil war strychnia was administered quite extensively, by several of the medical officers, in the chronic fluxes. Heroic doses, given apparently with a view to some imagined specific action, were ventured upon by at least one physician; but for the most part the alkaloid was given in tonic doses, and often in combination with quinia or iron, or both. Used in this way, the majority of those who employed it appear to have obtained beneficial results in suitable cases, but a few report that they were disappointed, probably because they expected too much.‖

Undoubtedly strychnia is, next to quinia, the most valuable of the tonics that can be employed in those cases of flux in which the use of tonics is indicated; but modern knowledge of its physiological action, as well as clinical experience, would seem to establish that

---

* E. GEDDINGS—*Note on dysentery, and the employment of nux vomica and its preparations in the treatment of that disease*, North American Archives of Med. and Surg. Sci., Vol. I, 1834–5, p. 123. His cases were observed at the Baltimore Infirmary during the fall of 1834. He commenced "by administering the nux vomica in powder, in doses of seven grains, three times a day, as recommended by Vaux of Ipswich, England." He also tried the alcoholic extract in 2-grain doses, thrice daily, and "strychnia, given in form of an acetate, in doses of one twelfth to one sixth of a grain, formed by dissolving the strychnia in acetic acid." He was, however, "inclined to prefer the powder, and next to that the extract," rather than the alkaloid—p. 127. He remarks: "To expect it to perform the part of a specific would be an absurdity, nor would it be reasonable to expect much from it in the acute stage of dysentery. But after suitable depletion, and especially, when the disease is verging upon a chronic form, we doubt not it will be found useful"—p. 128.

† W. M. CORNELL—*Ten cases of epidemic dysentery successfully treated with nux vomica*, The Charleston Med. Jour. and Review, Vol. IV, 1849, p. 295. The epidemic referred to occurred at the village of T—— (not otherwise designated) in the fall of 1848. He was induced to try it by reading the account given by ARMSTRONG of the practice of VAUX: "I gave it in the full dose of seven grains, thrice a day, to adults, and from one to three or four grains to children, in proportion to the age. The result was most happy. Not a patient who was treated with this medicine died. It was prescribed in ten cases, within three or four weeks, and all recovered. * * * I tried the strychnine; but on the whole, much preferred the powdered nux to that. * * * The nux was usually continued till it produced its characteristic symptoms, and at this period, and often before, it checked the disease"—p. 297 This paper is cited by G. B. WOOD—Vol. I, p. 723, *op. cit.*, p. 671, *supra*—who, however, prudently remarks: "It should never be used in the acute febrile state of the sthenic form of the disease."

‡ The alcoholic extract has been commended especially by NEVINS—*Employment of nux vomica in the diarrhœa of exhaustion*, The London Med. Gaz., Vol. XLII, 1848, p. 1035—and VOGT—*loc. cit.*, note ‡, p. 806, *supra*. The latter writer regards it chiefly as a tonic.

§ Among those who have preferred strychnia, I may mention, in addition to those already cited in note ¶, last page, JAMES F. DUNCAN—*Clinical lectures. Diarrhœa*, &c., The Dublin Med. Press, Vol. XIX, 1848, p. 274—who especially recommends it in those diarrhœas consecutive to "ordinary dysentery," in which there is "absence or deficiency of bile in the evacuations."

‖ Favorable reports of its employment were published by M. O. HEYDOCK—*Disease in Camp Douglas*, Chicago Med. Examiner, Vol. III, 1862, p. 517; W. C. OTTERSON—*Remedies for camp diarrhœa*, Amer. Med. Times, Vol. VI, 1863, p. 192; BROWER—*loc. cit.*, p. 779, *supra;* KEMPSTER—p. 346, *op. cit.*, p. 493, *supra;* E. H. PETTENGILL—*Case of chronic diarrhœa cured by the use of strychnia*, Trans. of the Vermont Med. Society for the years 1867 and 1868, p. 70; C. W. DAVIS—*Treatment of diarrhœa*, Amer. Med. Times, Vol. VIII, 1864, p. 154; and R. P. KENDALL—*A few remarks upon the use of heroic doses of strychnia in chronic diarrhœa, during the years 1862–63–64–65, in the United States service*, Cincinnati Lancet and Observer, Vol. X, 1867, p. 263. The last named physician ventured to give the alkaloid in the dose of ¼, ⅓ or even ½ grain; in one case even he gave ⅔ grain. The larger doses were never given oftener than once in twenty-four hours. He appears to have expected to observe symptoms of the toxic action of the drug before the flux was benefited, for he writes: "The specific effects of the strychnia did not manifest themselves until half-grain doses were reached;" and again: "In the case where ⅔ were given, the patient had no discharge for twelve hours. The specific effects were quite violent for two hours—commencing in twenty minutes after exhibition." He claimed that "the result was very decidedly good in every case but one." In the tract of STILLÉ—p. 380, *op. cit.*, p. 650, *supra*—strychnia or the tincture of nux vomica is recommended only "if a relaxed atonic condition of the anus exists." I myself—p. 261, *op. cit.*, p. 606, *supra*—classed strychnia with the remedies that "are of value in some of the varieties" of chronic flux, "and have hence been perhaps too recklessly administered in all cases." I expressed the opinion that "in cases accompanied by general muscular relaxation, with loss of appetite, and without marked abdominal pain or tenderness, nux vomica, or some of its preparations, will be found exceedingly useful." See also my remarks on the subject in *Circular No.* 6—p. 126, *op. cit.*, p. 571, *supra:* "Very generally it was combined with quinine, or with quinine and iron, and proved valuable in many atonic and paralytic conditions of the bowels, but was far from being of general availability in the treatment of severe chronic cases." On the other hand, BROWN—p. 81, *supra*—reports that he tried strychnia only to be disappointed; and S. K. TOWLE—*Notes of practice in the U. S. A. general hospital, Baton Rouge, La., during the year* 1863, Boston Med. and Surg. Jour., Vol. LXX, 1864, p. 58—having been induced to make use of it by the reported success of a friend, writes: "But though I thought I saw much improvement in some cases in restoring tone to the enfeebled intestines, yet I was not as well pleased with strychnine as from his reports I hoped I might be."

it is more than a mere tonic.* Its characteristic action upon the nervous system, and the beneficial results which have been obtained from its administration in various paralytic affections, should lead us to anticipate that it would be useful in the treatment of those paralytic conditions of the muscular coat of the intestines which so frequently occur in the advanced stages of dysentery and during the chronic fluxes. I refer not merely to paralytic states of the rectum and sphincter ani, but to those which occur in other parts of the intestine, especially the colon. These local paralyses favor fæcal accumulation in the affected parts, and this in turn gives rise to local irritative and inflammatory processes; periods of constipation alternating with continual recurrences of the flux hence result.

Savignac, who has drawn attention to the utility of nux vomica in the paralysis of the lower extremities that sometimes follows dysentery, has extended its employment also to the class of cases just mentioned.† For this purpose he prefers the powdered nux to its extract or the salts of strychnia, for the reason that, being less soluble, it may be hoped to reach all parts of the alimentary canal and to exercise its beneficial influence directly upon the paralyzed muscular coat. Of this powder he recommends daily from sixty centigrammes to a gramme, which latter quantity should not be exceeded, and he advises that it should be combined with powdered canella. Only in the consecutive paralyses of the limbs does

* Rapidly absorbed into the blood, the administration of strychnia, even in moderate doses, produces an increase of the arterial tension, apparently the consequence of a contraction of the muscular coat of the bloodvessels. At the same time it greatly augments the activity of the reflex actions of the spinal cord, and in sufficient doses produces convulsions and death. It probably exerts no influence on the brain; the coma that sometimes accompanies cases of fatal poisoning being apparently caused by the previous circulatory disturbances. It is somewhat slowly eliminated from the blood by the kidneys, for it can be detected unaltered in the urine several days after the ingestion of a considerable dose. It would occupy too much space to discuss this interesting and important subject in any detail. I refer the reader especially to the works of STILLÉ, Vol. II, p. 178, *op. cit.*, p. 711, *supra;* the HUSEMANNS—p. 376, *op. cit.*, p. 766, *supra*, and p. 505, *op. cit.*, p. 780, *supra;* H. C. WOOD—p. 282, *op. cit.*, p. 675, *supra;* and BUCHHEIM—p. 455, *op. cit.*, p. 727, *supra*—which give good abstracts of the subject, with references to the literature of the physiological action of the drug, its toxicology and its therapeutical use in paralytic conditions. Among the more recent investigations into its physiological action, which I have consulted, I may mention especially those of BROWN-SÉQUARD—*Exp. researches applied to physiology and pathology*, New York, 1853, p. 58; KÖLLIKER—S. 239, *op. cit.*, p. 746, *supra;* CLAUDE BERNARD—*Leçons sur les effets des substances toxiques et médicamenteuses*, Paris, 1857, p. 356; MARTIN-MAGRON et BUISSON—*Action comparée de l'extrait de noix vomique et du curare sur l'économie animale*, Jour. de la Physiologie, T. III, 1860, p. 117 *et seq.;* G. VALENTIN—*Versuch einer physiologischen Pathologie der Nerven*, Abth. II, Leipsic, 1864, S. 320; O. SCHULTZEN—*Strychningehalt des Upas tieuté, Uebergang des Strychnins in den Harn*, Archiv für Anat., Physiolog. und wiss. Med., Jahrg. 1864, S. 498; C. HEINEMANN—*Ueber den Einfluss der Strychninvergiftung auf die Bewegungen des Froschherzens*, Virchow's Archiv, Bd. XXXIII, 1865, S. 394; A. I. SPENCE—*On the mode of action of strychnia*, Edinburgh Med. Jour., Vol. XII, Part I, 1866, p. 44; A. VULPIAN—*Remarques touchant l'action de la strychnine sur les grenouilles*, Archives de Physiologie, T. III, 1870, p. 116; S. MAYER—*Ueber die Einwirkung des Strychnin auf das vasomotorische Nervencentrum*, Stricker's Med. Jahrb., Jahrg. 1872, S. 111; A. FREUSBERG—*Ueber die Wirkung des Strychnins und Bemerkungen über die reflectorische Erregung der Nervencentren*, Archiv für exp. Path. u. Pharm., Bd. III, 1874–5, S. 204 *et seq.;* and F. A. FALCK—*Brucin und Strychnin*, Vierteljahrsschrift für gerichtliche Med., Bd. XXIII, 1875, S. 78.

† When discussing the occurrence of paralysis in connection with dysentery—p. 412, *supra*—I inadvertently omitted to refer to the observations of SAVIGNAC, although I was well acquainted with them. This author—p. 190, *op. cit.*, p. 620, *supra*—under the heading *Paralysies dysentériques*, states that these affections may involve sensation, motion, or both. The most common variety is a paraplegia in which motion only is impaired: recoveries in the course of a few months are frequent, but sometimes it persists. He had observed paralysis of but one lower extremity in several sailors who had suffered with dysentery during the Crimean war, and had observed incomplete paralysis, or at least considerable muscular debility of both lower limbs, in several individuals who had contracted dysentery during the expedition to Mexico; but these latter cases had suffered also from marsh fever, or even yellow fever, one of them from articular rheumatism, so that he was not very sure of the part that dysentery played in the causation of the disease. In a subsequent memoir—*Des paralysies qui accompagnent et suivent la dysenterie et les coliques sèches, et de leur traitement par la noix vomique*, read to the Acad. Imp. de Méd., April 9, 1867, L'Union Médicale, T. III, 1867, p. 200 *et seq.*—these views are elaborated with more detail, and a case is recorded in which the patient, who contracted dysentery in Mexico, suffered from progressive paralysis at first of the lower and afterwards of the upper extremities. The case terminated fatally, and on the autopsy lesions of the spinal cord were observed, the description of which I cite on account of the rarity of similar observations: "Le bulbe rachidien ne présente rien de particulier. Mais des lésions importantes se découvrent dans la mœlle. En effet, le renflement cervical est le siége d'un ramollissement blanc, sans injection sanguine, constituant la matière qui le forme en état de diffluence légère. Au-dessus et au-dessous du renflement cervical, dont les émergences nerveuses ne participent pas au ramollissement, le cordon rachidien offre son aspect et sa consistance ordinaires. Dans le renflement lombaire ou crural, ramollissement bien plus considérable encore; en cet endroit la mœlle, après incision de ses enveloppes, se montre en pleine diffluence, blanche, sans mélange de sang. Ce ramollissement se propage, quoiqu' à un moindre degré, un peu au-dessus du renflement lombaire, et beaucoup au-dessous, en intéressant jusqu' aux nerfs terminaux formant le faisceau dit *queue de cheval*." In another case of dysentery, in which paralysis of the lower limbs preceded death, SAVIGNAC found "au niveau du renflement lombaire, non pas, à vrai dire, un ramollissement, mais néanmoins plus de mollesse que dans le reste du cordon rachidien;" and also "une assez forte injection sanguine de ce renflement lombaire." I leave it to my readers to judge just how much these observations are probably worth, remarking only that no histological investigation appears to have been undertaken, and that the time that elapsed between death and the autopsies is not recorded. For his account of his later experience with nux vomica in chronic fluxes and his views as to its mode of operation, see p. 241 *et seq.* In his earlier work—p. 390, *op. cit.*, p. 620, *supra*—he stated that he had not yet made any very conclusive observation on the subject. As to his preference for nux vomica rather than strychnia, I must confess he appears to me to base it on exceedingly illogical grounds. If his speculation "sur l'origine rachidienne et la nature paralytique de la dysentérie" had, even in his own mind, any substantial basis, he would surely expect to reach the diseased spinal cord more speedily and effectually by the soluble and active sulphate or acetate of strychnia than by the powdered nux, to which he gives the preference on grounds which seem to indicate that he unconsciously inclines to a belief in the purely local nature of the disease, which is quite incompatible with the theories he has so eloquently advocated. Compare with the paper cited above one entitled *De l'emploi de la noix vomique contre la dysentérie et contre les paralysies dysentériques*, (par le docteur D. DE SAVIGNAC,)—Bull. Gén. de Thér., T. LXXIII, 1867, p. 193—which appears to be an abstract of it.

he prefer the alcoholic extract or the salts of strychnia; I confess, however, that I am not convinced by his arguments that the salts of strychnia are not likely to be equally efficacious in the intestinal paralyses. For this purpose the sulphate or acetate of strychnia may be given, preferably in solution, at first in the dose of one-thirty-second to one-sixteenth of a grain thrice daily, and gradually increased to one-tenth or even one-eighth of a grain. Larger doses should be regarded with suspicion, and even those last mentioned will require careful watching in order that they may be promptly diminished or discontinued on the occurrence of toxic symptoms.* If, however, strychnia is selected merely as a tonic, in cases uncomplicated by external paralysis, and in which there is no good reason for suspecting the existence of any paralytic condition of the intestine, the smaller doses named will be sufficient, and may advantageously be combined with quinia, iron, or both.

Among the *mineral tonics* deserved preëminence has long been enjoyed by the *chalybeates*, but their use in the fluxes has already been sufficiently discussed in previous pages of this work.† Next in importance stand the *mineral acids*, which were early introduced into medicine by the iatro-chemical school. First discovered, *sulphuric acid* was first brought into medicinal use. The red, green and white oils of vitriol, and a host of dulcified oils, waters, spirits and elixirs of vitriol, named generally after the chemists who devised them, were added to the resources of the physicians of the fifteenth, sixteenth and seventeenth centuries. Already Basil Valentine had a dulcified oil of vitriol,‡ and when Paracelsus wrote, the role of the preparations of sulphuric acid in the treatment of disease had become a subject of fierce debate. That erratic speculator, who lauded his own aquæ and spiritus vitrioli in epilepsy and other nervous diseases, in affections of the womb and in internal obstructions and inflammations, insisted that the utmost caution should be used in the case of the oil. It should never be given alone, but always diluted and combined with other medicinal preparations; nor should it be administered if the stomach was inflamed or contained bile; but with these precautions it was an excellent remedy that might be resorted to in anorexia and in fevers of every kind.§

Subsequent iatro-chemists made much of the use of the preparations of sulphuric acid in fevers, especially in malignant fevers. Its acidity was directly opposed to the alkaline putrescence of the humors; its tenuity was such that it could penetrate to all parts of the system, reach the interior even of organs that had become the seat of the most obstinate pathological obstructions, and neutralize the putrid humors there. Analogy early led them to extend these principles to the treatment of malignant, as well as of ordinary, dysenteries, and Angelus Sala went so far as to invent a vitriolated antidysenteric syrup and a vitriolated

---

* H. C. WOOD—*loc. cit.*, note *, last page—observes that "death has occurred from an irregularity in the solution of the pills in the alimentary canal and the consequent simultaneous letting loose of a large amount of the alkaloid." For this reason he advises that when it is desired to "push it until its physiological effects are manifested," it should always be administered as the sulphate in solution. This suggestion should never be disregarded. The danger of venturing upon such doses as were employed by KENDALL—see note ‖, p. 808, *supra*—will be appreciated when it is remembered that half a grain has proved sufficient to destroy life. Consult on this subject TAYLOR—p. 712, *op. cit.*, p. 791, *supra*—and the works of the HUSEMANNS, cited note *, last page.

† See pp. 762, 771, 785 and 805, *supra*.

‡ I have already expressed my regret that I have been unable to examine the writings of BASIL VALENTINE, except the *Chariot of Antimony;* but JAMES—Art. *Vitriolum*, Vol. III, *op. cit.*, p. 690, *supra*—states that he had a dulcified oil of vitriol, and MANGETUS—T. II, p. 766, *op. cit.*, p. 736, *supra*—attributes to him a spiritus vitrioli antepilepticus, showing that the notion of the efficacy of this acid in epilepsy dates back to his time.

§ PARACELSUS—*De naturalibus rebus*, Lib. I, Cap. 8, T. II, p. 202 *et seq.*, *op. cit.*, p. 336, *supra*—describes red, white and green oils of vitriol, besides aquæ vitrioli, spiritus vitrioli and a special antidote to epilepsy, *vitrioli contra caducum præparatio*. His whole discussion of the subject is characterized by his usual brutal violence. Rival chemists are *imperiti laboratores* for whom he has nothing but denunciation. Some of them have dared to use the pure oil of vitriol in disease; they say much of its virtues, but little is confirmed by experience. He has examined into the matter, and has found that those who boast that they have worked miracles with this oil have foully lied: "Vidi ego et comperi, eos qui miraculosa se oleo isto fecisse jactitant, turpiter mentitos esse." As for the Galenical physicians who refuse to use these preparations at all, they are the accursed priests and Levites who pass the sick man by on the other side, leaving him to the good Samaritan, PARACELSUS, to cure. They deserve the fires of Gehenna, from which there is no redemption; they are possessed by the Devil, whom they serve, and who hardens their hearts against all truth.

antidysenteric confection, for which he claimed special virtues in this disease.* A fresh impetus was given to the use of these preparations by the speculations of Kircher, who suggested the employment of spirit of vitriol as a parasiticide, peculiarly fitted to destroy the vermiculi he imagined to be the cause of pestilential diseases.† His methods were adopted by several of the advocates of the animated pathology, and Christian Langius taught that the spirit of vitriol was more potent in the destruction of the verminous putridity that, according to him, caused diarrhœa and dysentery, than any other medicament, except, perhaps, the hoof of a horse sliced thin and fried in butter, which had been lauded as an arcanum by Van Helmont.‡

After the discovery of *nitric* and *muriatic acids*, these were brought into use for the same purposes as sulphuric, though by no means to the same extent.§ Even after the animated pathology had fallen into oblivion these acids continued to find favor among the so called antiseptic remedies employed in malignant fevers and dysenteries.‖ But about the commencement of the present century other notions concerning the utility of the mineral acids in the fluxes were brought forward. McGrigor employed nitric acid in the treatment of dysentery partly as an astringent, partly as a substitute for mercury, and on account of its supposed action on the liver. This method enjoyed for a time considerable popularity, and was adopted by Annesley, who regarded it as particularly serviceable in dysenteries attended with disease of the liver and a depraved secretion of bile.¶ It has continued to be occasionally employed from time to time, and if the speculation of Bailey,

* See ANGELUS SALA—*Anatomia vitrioli* and his *Diss. de natura, proprietate et usu, spiritus vitrioli*, Opera, p. 358 *et seq.*, and p. 404 *et seq.*, Ed. cited p. 776, *supra*—who gives methods for the preparation of, 1, ros vitrioli; 2, aqua vitrioli secunda; 3, liquor vitrioli acidus primus, vulgo spiritus vitrioli; 4, spiritus sulphuris vitrioli et liquoris acidi primi rectificatio; 5, liquor vitrioli acidus secundus, vulgo oleum vitrioli appellatus; besides formulæ for a variety of nostrums into which one or another of these forms of sulphuric acid entered as ingredients, such as his liquor antepileptieus, liquor cardiacus, liquor restaurativus, liquor contra prunellam, liquor contra pestem, and the two antidysenterie preparations mentioned in the text. His confectio contra dysenteriam consisted of the spiritus vitrioli acidi, combined with his laudanum—see p. 736, *supra*—lachrymæ draconis and conserve of roses; his syrupus dysentericus vitriolatus was prepared by boiling tormentil root, myrobalans, sanguinaria seed and red rose leaves in water and adding spiritus vitrioli and sugar. The doctrine of the action of the various forms of spiritus vitrioli in pestilential and other fevers, sketched in the text, will be found fully elaborated on pp. 360, 378 and 417. So, likewise, I may cite OSWALD CROLL—p. 282, *op. cit.*, p. 736, *supra*—who had a stomachic oil of vitriol that was useful in fevers and abnormal thirst, served as a prophylactic against pest if mixed with sugar and electuary of juniper, and was useful in all putrid diseases and obstructions: "Post evacuatum corpus cum theriaca seu aquis appreprietatis fere in omnibus morbis exhiberi potest, aciditate enim sua putredinem omnem arcet, partium vero tenuitate obstructiones pellit"—p. 286. For details with regard to the preparations of sulphuric acid in use in the latter part of the seventeenth century and the early part of the eighteenth, I may refer to MANGETUS—Vol. II, p. 761 *et seq.*, *op. cit.*, p. 736, *supra*.

† A. KIRCHER—p. 185, *op. cit.*, p. 369, *supra*. In the use of sulphuric acid he professedly followed PARACELSUS, for, after naming the Galenical antidotes to pest, he adds: "Hisce accenset Theophrastus spiritum vitrioli una cum aqua ex oxali seu acetosa extracta, sudandi gratia assumptum;" and then explains, "sunt enim tria in vitriolo consideratione dignissima, quibus virulentus hospes omnino prosternitur, extinguiturque. Siccitate sua naturæ peregrina putredo exeditur; astringendi vero vi laxatarum partium colligatio roburque ad externam vim propulsandam conceditur, tandem vi caloris nativi, externus advenieus calor prorsus superatur." CHRISTIAN LANGIUS—p. 467, *op. cit.*, p. 369, *supra*—after explaining that VAN HELMONT'S nostrum, mentioned in the text, is probably useful, because its sulphurous vapor is fatal to the verminous putridity, remarks: "De nostro hoc tantum addimus, quod illa remedia præter ea, quæ animatam corruptionem peculiariter extinguunt, et fermentationis malignæ tyrannidem compescunt, suum quoque hic sibi locum vendicent, quæ supra (p. 292) in curatione exulceratarum faucium ac tonsillarum laudata fuerunt. Ubi præsertim usus olei seu spiritus vitrioli tanquam summum specificum contra hujuscemodi ulcerationes et inflammationes insinuatus fuit." He therefore recommends the use of a julep suitably impregnated with the oil or spirit to be taken internally, and also the use of enemata containing enough of the same to give a slightly acid taste.

‡ The passages in which VAN HELMONT recommends the nostrum referred to will be found in the tracts *Pylorus rector*—p. 231—and *Ignota actio regiminis*—p. 340, *op. cit.*, p. 488, *supra*. In both he explains, however, that you must be careful not to select a young mare in the rut, for her hoof would be fatal: "Sed si bestia lasciviat, tunc ejus ungula est dysentericis lethalis." The former of these tracts contains the pathology of dysentery as understood by this author. The pylorus is the governor (rector) of the whole digestive economy, intestinal as well as gastric; diarrhœa and dysentery result when there is a disagreement between the pylorus and the bile—p. 229. The object of treatment is to appease the raging pylorus, (furorem pylori sedari,) and for this purpose two yolks of hard-boiled eggs, tempered with rose-vinegar, will also answer excellently. Elsewhere—*Potestas medicaminum*, p. 476—he commends another admirable remedy: A towel soaked in the blood of a hare hunted to death may be dried and pieces of it administered in wine; or the hare may be dried in smoke and pieces of it given in drink, as is done by the German soldiers; and this is an infallible cure. It must be remembered that, for VAN HELMONT, diseases were entities, "sed morbus est ens reale"—*Ignotus hospes morbus*, p. 492—and that he ridiculed the idea that the intestines were ulcerated in dysentery, which in that event would be incurable—*Pleura furens*, p. 397.

§ Nitric acid was known to PARACELSUS, who sometimes called it *aqua fortis—Archidox.*, Lib. II et III, Vol. II, p. 7—sometimes *aqua regis—De præparationibus*, Lib. I, same Vol., p. 82, *op. cit.*, p. 336, *supra*. Muriatic acid was first isolated by GLAUBER—see note ‡, p. 706, *supra*.

‖ See, for example, G. WEDEKIND—*Nachrichten über das französische Kriegsspitalwesen*, Bd. I, Leipsic, 1797, S. 189: "Allgemeine antiseptische Mittel sind, die Säuern, besonders die mineralischen." Compare also his essay *Ueber die Ruhr*, Frankfort, 1811, S. 86, where vitriolic acid, sulphur, salmiac, camphor, wax and arnica are praised as antiseptic measures especially useful in dysentery.

¶ JAMES MCGRIGOR—*A memoir on the state of health of the 88th regiment, and of the corps attached to it, from 1st June 1800 to the 31st May 1801, as originally presented to the Medical Board, Bombay*, Edinburgh Med. and Surg. Jour., Vol. I, 1805; I cite the 2d Ed., p. 281—also p. 185, *op. cit.*, p. 713, *supra*—where he mentions that DEAN and BELLARS of the 86th regiment had treated several hundred cases of dysentery solely by the nitric mixture and baths. ANNESLEY—Vol. II, p. 295, *op. cit.*, p. 621, *supra*—thought it especially useful after mercurials have been used, and when the disease becomes subacute or chronic; it was still more useful when combined with opium.

that it is possessed of antiperiodic powers were true* it might be resorted to with advantage in fluxes complicated with malarial conditions.

Nitro-muriatic acid, to which attention was directed by Scott, who claimed that it is a powerful remedy in acute and chronic hepatitis,† has, however, replaced nitric acid to a certain extent. Its use in dysentery was regarded with favor by Parkes and Martin, and it is still occasionally employed in certain varieties of chronic diarrhœa.‡ Another substitute for nitric acid is the *nitrous-acid mixture*, which Hope employed in the treatment of dysentery at the beginning of the century, and Bryan used with success in the Philadelphia epidemic of 1847.§ This mixture enjoyed the confidence of Tripler in the treatment of chronic dysentery, and quite recently H. C. Wood has declared that he obtained excellent results with the original formula in certain diarrhœas, although he failed absolutely with the commonly-employed substitute in which ordinary nitric acid is used instead of the fuming acid.‖ Meanwhile the old use of dilute sulphuric acid in diarrhœa has been revived by Anthony Todd Thomson, who found followers in Griffith and numerous other physicians, especially in England, from 1851 to 1854.¶ It is probably more extensively used in the treatment of the fluxes at the present time than any other mineral acid.

During our civil war the mineral acids were resorted to by a number of military surgeons. The commendation of Tripler induced some to employ Hope's mixture; but the aromatic sulphuric acid was undoubtedly the most popular preparation, and was generally combined with laudanum. These acids were administered not only in the chronic fluxes,

* G. MENDENHALL—*On the use of nitric acid as an antiperiodic*, The Western Lancet, Vol. XV, 1854, p. 472: "The facts upon which this paper is based, are taken mainly from an inaugural dissertation, presented to the Trustees and Faculty of the Miami Medical College, for the degree of Doctor of Medicine, by E. T. BAILEY, M. D., of Emmettsville, Indiana." Observations in confirmation of those of BAILEY have been brought forward by I. A. COONS—*Report of the committee on a substitute for quinine*, Trans. of the Ohio State Med. Society, June, 1856, in The Ohio Med. and Surg. Jour., Vol. IX, 1856-7, p. 275; W. A. HAMMOND—*Nitric acid in intermittent fever*, The Maryland and Virginia Med. Jour., Vol. XVI, 1861, p. 104; and B. BROWN—*Some remarks on the adynamic type of remittent fever and its treatment with nitric acid*, The Amer. Jour. of the Med. Sci., Vol. XXXIX, 1860, p. 43. It is needless to remark that this practice has not yet supplanted quinia.

† H. SCOTT first recommended the use of nitric acid for this purpose in 1796 in letters which have been printed by T. BEDDOES—*A collection of testimonies respecting the treatment of the venereal disease by nitrous acid*, London, 1799, p. 1 *et seq.* In one of these letters he remarks, after describing the method by which the nitric acid was made: "As the nitre that I used contained about six per cent. of sea salt, it will be evident that the acid that I obtained is not a pure acid of nitre, but it is a mixture of nitric acid, and oxygenated muriatic acid, or it is an aqua regia, in which the marine acid bears a small proportion to the nitric acid"—p. 9. In a subsequent paper—*On the internal and external use of the nitro-muriatic acid, in the cure of diseases*, (read March 4, 1817,) Medico-Chirurg. Trans., Vol. VIII, 2d Ed., 1820, p. 175—he mentions that he long believed the good effects of the mixture were due to the nitric acid only; but when he procured some of the pure acid he was disappointed in the results, and therefore returned to a mixture, at first of three parts of nitric acid to one of muriatic, and subsequently employed them in equal weights. He introduced the baths of this acid, which were afterwards employed also by ANNESLEY—*loc. cit.*, note ¶, last page: see also, on the use of these baths, G. J. GUTHRIE—*On the effects of the nitro-muriatic acid bath in several surgical diseases*, The London Med. Repository, Vol. VIII, 1817, p. 449.

‡ PARKES—p. 151, *op. cit.*, p. 682, *supra*. MARTIN—p. 465, *op. cit.*, p. 621, *supra*. H. C. WOOD—p. 98, *op. cit.*, p. 675, *supra:* "In those forms of chronic diarrhœa in which the disease is really an intestinal dyspepsia, nitro-muriatic acid may be of the utmost service, benefiting and even curing cases which have resisted all other treatment."

§ THOMAS HOPE—*Observations on the effects of nitrous acid and opium in the cure of dysentery*, The Med. and Phys. Jour., Vol. III, 1800, p. 413, and *Observations on the powerful effects of a mixture containing nitrous acid and opium in curing dysentery, cholera, and diarrhœa*, The Edinburgh Med. and Surg. Jour., Vol. XXVI, 1826, p. 35. His formula, as given in the latter article, was: "℞. acidi nitrosi ʒj, mist. camphor. ʒviij. Misce et adde tinct. opii, gtt. xl. Sig. One fourth part to be taken every three or four hours." He insisted strongly upon the use of what is still called nitrous acid in the shops, or sometimes fuming nitric acid, (really a solution of pernitric oxide in nitric acid,) and declared that ordinary nitric acid with opium produced no good effects. JAMES BRYAN—*Epidemic dysentery*, The New York Jour. of Med., Vol. X, 1848, p. 49.

‖ TRIPLER—p. 34, *op. cit.*, p. 691, *supra*. H. C. WOOD—p. 97, *op. cit.*, p. 675, *supra*—after insisting upon the point made in the text, remarks: "Made in this way, and used whilst fresh, Hope's camphor mixture is a very efficient though disagreeable remedy in diarrhœas connected with disordered secretion of the liver and other glands of the alimentary canal." It is my duty to add that I have no confidence whatever in this view of the matter.

¶ ANTHONY TODD THOMSON—*The London Dispensatory*, 1837, p. 762; I have not seen this edition, our library only possessing that of 1815, and quote from GRIFFITH—cited *infra*—who remarks: "I would here call the attention of your numerous readers to the fact of this remedy having been recommended by the late Dr. Anthony Todd Thompson in diarrhœas. In the 'London Dispensatory' of 1837, page 762, there is an article on the Diluted Sulphuric Acid, in which he states, 'that when combined with mucilages, it has been beneficially given in passive diarrhœas, operating on the relaxed nervous coat of the intestine as an astriogent. The usual dose is from ten to thirty minims, but this dose may be very often repeated.'" WM. GRIFFITH—*Treatment of diarrhœa by sulphuric acid alone*, The Lancet, 1851, Vol. II, p. 334—reported several cases of diarrhœa successfully treated in this way, and some years later—*Sulphuric acid in diarrhœa*, Med. Times and Gaz., 1862, Vol. I, p. 68—had so far forgotten his original article as to write: "Having been the first person to introduce to the profession the treatment of diarrhœa by sulphuric acid, when I published some cases in 1851," &c. Corroborative testimony has been published by J. ASHBURY SMITH—The Lancet, 1851, Vol. II, p. 359; G. B. PAYNE—same Vol., p. 382; E. SHEPPARD—Provincial Med. and Surg. Jour., Vol. XVI, 1852, p. 471; J. J. MITCHELL—same Vol., p. 566; J. L. VANDERVOORT—The New York Méd. Times, Vol. II, 1852-3, p. 75; JOHN HILL—The Med. Times and Gaz., Vol. XXVI, 1852, pp. 197 and 578; R. NEALE—same Vol., p. 472; F. COLLINS—same Vol., p. 521; J. M'DONNELL—same Vol., p. 600; W. BRAITHWAITE—same Vol., p. 629; J. MANN—same page; C. M. MILLER—The Lancet, 1852, Vol. II, p. 323; JOHN DENNY—same Vol., p. 556; S. W. NORTH—The Med. Times and Gaz., Vol. XXVII, 1853, p. 159; GOODEVE BOWRA—The Lancet, 1854, Vol. I, p. 98; F. M. DAVIDSON—same Vol., p. 404; and ANDREW CLARK—Med. Times and Gaz., 1862, Vol. I, p. 10.

but in acute diarrhœa and in the advanced stages of acute dysentery. They were undoubtedly frequently useful, but achieved no such striking success as to lead to their general employment.* Nor, when the little that is known with certainty of the mode in which medicinal doses of the mineral acids act is considered, will it appear surprising that anything like their indiscriminate use in the fluxes so often proves inefficient or injurious.

In view of the strong affinity of these acids for bases and the prompt manner in which they combine with them, in such mixtures as the alimentary contents, it is exceedingly improbable that they can make their way in the free state very far into the intestinal canal to neutralize abnormal alkalinity or exert directly a local astringent action, as has been fondly hoped even in modern times.† The old doctrine that they act by diminishing the alkalinity of the blood, and in this way restrain septic tendencies, still survives; even such observers as Bence Jones and Headland maintain that the alkalinity of the blood may thus be diminished.‡ But this view is not supported by the evidence of actual experiment, and, as Buchheim has suggested, the quantity of the mineral acids that can be safely administered for medicinal purposes is hardly sufficient to go very far in this direction.§ The refrigerating effect they are said to produce in fevers is probably a mere phenomenon of sensation due to their local impression upon the mouth, pharynx and stomach; at least thermometric observations, to show that an actual lowering of temperature results from their use, have not yet been put in evidence.

The primary and most important action of medicinal doses is undoubtedly to increase the activity of digestion. In the languid condition of this function that so often accompanies acute and chronic fluxes, this property of the acids is often exceedingly useful. With the increased activity of digestion and assimilation that often follows their moderate use, the strength and general condition of the patient not infrequently improves, and with improved health the flux diminishes or ceases. Moreover, as recent experiment appears to confirm the opinion that nitro-muriatic acid increases the hepatic secretion,‖ it is probable that it may be advantageously selected in acholic conditions. Unfortunately, however, the continued use even of moderate doses of the mineral acids after temporarily improving is prone in the end to disorder the digestive processes and to produce gastric catarrh or even diarrhœa.¶ A protracted course of acid treatment is therefore seldom permissible.

The old use of sulphuric acid as a parasiticide has been revived by some of those who believe the fluxes to be caused by specific bacteria;** but the speculation that it can act in this way is unsupported by facts. If bacteria in the blood are intended to be killed, we know too well the acid can never be made to reach them; but it is not as generally under-

* Reports will be found in Section II favorable to the use of nitric acid by DEBRULER—p. 42, *supra*, and TAYLOR—p. 87; of Hope's mixture by TUTTLE—p. 90; of dilute or aromatic sulphuric acid by SCHÜSSLER—p. 44; BLAKESLEE—p. 76; WALTON—p. 88; COFFMAN—p. 97; and BRADT—p. 100; of the mineral acids, without specifying which, by PENROSE—p. 45, and GRANGER—p. 86. Hope's camphor mixture is also recommended by BROWER—*op. cit.*, p. 779, *supra*, and aromatic sulphuric acid by KEMPSTER—*op. cit.*, p. 493, *supra*. For my own views, in 1863, on the use of the mineral acids in the fluxes, see p. 259, *op. cit.*, p. 606, *supra*.

† F. SCHNEIDER—*Dysenterie, rothe Ruhr, ihr Wesen und ihre Behandlung*, Leipsic, 1873, S. 30—recommends the use of sulphuric acid as an astringent in the advanced stages of dysentery, and also in hæmorrhagic cases for the arrest of the hæmorrhage.

‡ H. BENCE JONES—pp. 24 and 288, *op. cit.*, p. 804, *supra;* HEADLAND—p. 135, *op. cit.*, p. 790, *supra*.

§ BUCHHEIM—S. 175, *op. cit.*, p. 746, *supra*. I would refer the reader to this work especially for an excellent summary of the little that is positively known with regard to the physiological action of the dilute mineral acids. See, also, on the particular question referred to in the text, A. TRACHTENBERG—*Zur Frage über die Neutralisation überschüssiger Alcalien im Blute*, Inaug.-Diss., Dorpat, 1861.

‖ RUTHERFORD and VIGNAL—Experiment 30, *op. cit.*, p. 701, *supra*.

¶ See, on this subject, BUCHHEIM—S. 174, *op. cit.*—and NOTHNAGEL—S. 379, *op. cit.*, p. 746, *supra*.

** See, for example, the report of J. M. WOODWORTH—*The introduction of epidemic cholera into the United States through the agency of the mercantile marine*, &c., Ex. Doc. No. 95, 43d Congress, 2d Session, Washington, Government Printing Office, 1875, pp. 8 and 17—on the use of sulphuric-acid lemonade as a prophylactic against cholera: "There can be little doubt, despite the *dicta* of the last International Sanitary Conference, that *we possess in the mineral acids a certain means of prophylaxis against cholera*." For a recommendation of dilute sulphuric and other mineral acids as parasiticides in diarrhœa, see the paper of WM. JOHNSTON, cited note †, p. 804, *supra*.

stood as it should be, that the attempt to kill bacteria in the intestinal canal by any dose of sulphuric acid that can be administered by the mouth without danger to life is equally futile; and that the various forms of bacteria normally present in the stools, whether diarrhœa exist or not, are equally numerous and vivacious in the stools of those who have been taking sulphuric acid for days or weeks.

It is therefore chiefly, if not exclusively, as adjuvants to the digestive process that the mineral acids are useful in the fluxes. With this view they should be given only with the food and in moderate doses; ten to twenty drops are a sufficient dose of diluted or aromatic sulphuric acid,* of diluted muriatic acid or diluted nitric acid. The diluted nitro-muriatic acid does not keep well, and it is better, therefore, to prescribe the strong acid in the dose of five to eight drops and dilute it at the time of administration. These doses may be taken three or four times daily. To use them more frequently or to employ larger doses is only to risk unnecessarily the early development of gastric disturbance.

Dilute *phosphoric acid* has also been employed in the chronic fluxes, especially by Schneider,† but further observations are needed to show how far it is a desirable substitute for the other mineral acids in this class of cases.

In this place also the use of the *vegetable acids* in the fluxes may be mentioned; but as they are chiefly, if not exclusively, useful in cases complicated with scurvy or a scorbutic taint,‡ the discussion of their utility will be postponed to a subsequent chapter.

Aromatics.—The Greek physicians employed a great variety of aromatic drugs in the treatment of the fluxes. *Anise*, *fennel*, *cardamom*, *pepper*, *ginger*, *mint*, *cassia*, *cinnamon* and *spikenard* may be mentioned as prominent among the substances of this character with which they were acquainted, and one or more of these figure in most of the anodyne and astringent formulæ preserved by Galen, Ætius, Alexander of Tralles and Paulus Ægineta.§ The Arabians continued to use most of these substances in the same way, and added several others, among which *orange-peel*, *cloves*, *mace* and *nutmeg* may be particularly mentioned;‖ the last named substance subsequently acquired considerable renown as an antidysenteric.¶ Among the aromatics brought into use at a later period *capsicum*, *peppermint*, *lavender* and *canella* may be referred to.**

During the early part of the last century it was common to employ the culinary spices and ginger with wine and brandy as domestic remedies for the fluxes. Zimmermann earnestly protested against tolerating this practice in the early stages of dysentery, pointing out that, although the flux might thus be checked for a time, it presently returned, and that

* The aromatic sulphuric acid of our Pharmacopœia is the descendant of the elixir of vitriol of Mynsicht: see Mangetus—T. I, p. 807, *op. cit.*, p. 736, *supra*. In the modern preparation the sugar originally used is omitted, and ginger and cinnamon are the only aromatics retained.

† Schneider—S. 29, *op. cit.*, note †, last page.

‡ Savignac, indeed, did not hesitate to write of them—p. 393, *op. cit.*, p. 620, *supra:* "Les acides, en un mot, sont pendant et après la maladie, plus nuisibles qu'utiles aux dysentériques."

§ See the passages in these writers cited in notes § and ‖, p. 735, *supra*. Descriptions of the several substances named are given by Galen, Dioscorides and Paulus. The *mint* was probably our *mentha sativa*.

‖ *Orange-peel* and an oil prepared from it are mentioned by Ebn Baithar—Bd. II, S. 545, Ed. cited p. 704, *supra*. *Cloves* are mentioned by Paulus—Vol. III, p. 160, Ed. cited p. 624, *supra*—but are noticed by none of the earlier Greek writers. They are quite fully described by Serapion—*De temp. simp.*, Cap. 309, fol. 172, Ed. cited p. 806, *supra*—and other Arabian writers. Serapion also described *mace*—Cap. 2, fol. 121—and *nutmeg*—Cap. 161, fol. 145, *op. cit.* Here, too, I may allude to two animal substances which were long used in the fluxes very much in the same way as the aromatics. The first is *castor*, which was well known to the Greek physicians, and which Archigenes considered of such importance that he wrote a special treatise on its medical use; see Galen—*De simp. med. temp. ac fac.*, Lib. XI, Cap. 1, [Ed. Kühn, XII, 337.] It figures in several of the formulæ referred to in note §, *supra*, and Avicenna employed it to counteract the depressing influence of opium—see note *, p. 736, *supra*. *Musk* was introduced by the Arabian physicians. It is described by Serapion—Cap. 185, fol. 149, *op. cit.*, *supra*—and others. Long employed in the fluxes in the same way as castor, its use for this purpose is now quite obsolete.

¶ See, on this subject, note ††, p. 776, *supra*.

** *Capsicum* appears to have been brought to Europe shortly after the discovery of America; *canella* almost a century later. *Lavender* is already mentioned by the Abbess Hildegard in the twelfth century, and in the Rhyme of the School of Salerne, while *peppermint* was first brought into medicinal use in England about the close of the seventeenth century. See the *Pharmacographia*, pp. 406, 68, 428 and 433, Ed. cited p. 703, *supra*.

the condition of the patient was only aggravated by the vain attempt. It is to be regretted that such "stupid domestic remedies," as Zimmermann justly called them, are by no means banished from family use in our own day.* All these aromatics and the volatile oils to which they owe their virtues are local irritants, and should therefore be employed with a sparing hand in acute inflammations of the gastro-intestinal canal.† They may, however, be used with advantage in small quantities, during subacute or chronic fluxes without pain or fever, to give an agreeable taste to other medicines, and larger doses may sometimes serve a useful purpose by temporarily stimulating the flagging digestive functions, or by acting as carminatives to relieve flatus. Further investigations into the physiological action of the volatile oils may perhaps suggest for some of them a wider range of usefulness;‡ but the indications just sketched represent all that can as yet be considered as fully established with regard to their use in the fluxes. Undoubtedly slight diarrhœas often disappear promptly after the administration of alcoholic solutions of these substances; but even such cases can be more uniformly and promptly relieved by other measures.

RESINS, BALSAMS, OIL OF TURPENTINE and CAMPHOR.—A large number of resinous substances and balsams, such as *frankincense*, *myrrh*, *mastich*, *turpentine*, *styrax* and *opobalsam*, were regarded by the Greek physicians as possessed of calefacient and drying properties, and were combined with the remedies they administered in the fluxes.§ They also used them as external applications in the treatment of callous ulcers,‖ and this practice appears to have suggested their use in those fluxes in which such ulcers were supposed to exist in the intestines.¶ Moreover, as the fruit and other parts of the shrub from which mastich is derived had the reputation of being astringent, and a decoction of it was long employed with supposed benefit in the fluxes,** these virtues were subsequently assigned to its resinous exudation, which obtained, perhaps in this way, a sort of priority over the other drugs of this group. The Arabian and mediæval physicians employed these substances in the same way, and after the importation of the *balsams* of *Peru* and *Tolu* from America they, too, were occasionally employed for the same purpose.†† Even Degner believed that drugs of this class favored the cicatrization of intestinal ulcers, although he admitted that he had derived little benefit from them during the Nimeguen epidemic.‡‡

---

* ZIMMERMANN—Cap. VII, S. 161, *op. cit.*, p. 648, *supra:* "Alle Aerzte in der Schweiz, die an der Ruhr kranke Bauern in sehr verwirrten Umständen finden, haben dieses von dem Gebrauche stopfender Arzneyen, und dummer Hausmittel herzuleiten; aber insbesondere von den Muscatennüssen, Muscatenblüthe, Ingwer, Pfeffer, Wein, und Brandtwein, die freilich die Ruhr für eine Weile zurückhalten, aber bald darauf den Kranken in die gefährlichsten Uebel stürzen."

† And yet from time to time some particular aromatic is lauded as though it were an exception to this general rule. Thus SAVIGNAC—p. 394, *op. cit.*, p. 620, *supra*—writes of *canella:* "J'ai une grande confiance en la *cannelle* dans le traitement de la dysentérie, et j'en donne les préparations à toutes les périodes de la maladie. Stimulant puissant, on en proportionne la dose à la somme d'énergie que l'on veut communiquer quand les forces languissent ou quand l'adynamie se prononce." Now, frankly, I can no more accept this view than I can admit that it is possible to "communicate energy" by canella under any circumstances.

‡ See the sketch of the present state of knowledge on this subject in the work of BUCHHEIM—S. 564, *op. cit.*, p. 746, *supra*—who discusses these aromatic oils in the same group with oil of turpentine, &c., under the heading "Gruppe des Turpenthinöls."

§ See the accounts of these substances given by GALEN in the treatise *De simp. med. temp. ac fac.* According to him *frankincense* was also astringent, and therefore particularly useful to cœliacs and dysenterics—Lib. VII, Cap. 11, [Ed. Kühn, XII, 60;] *myrrh* was useful in expelling lumbricoids and favoring the cicatrization of ulcers—Lib. VIII, Cap. 17, [same Vol., 127;] *mastich* and *turpentine* he classed under the head of resins—p. 113. For his account of *styrax*, see p. 131; of *balsam*, same treatise, Lib. VI, Cap. 2, [Vol. XI, 846.] The juice of the balsam tree was known as *opobalsam*, while the twigs were called *xylobalsam*. The best opobalsam came from Syria—*De antidotis*, Lib. I, Cap. 2, [Vol. XI, 7,]—and was no other than the famous *balm of Gilead*. These substances figure in the formula referred to on p. 735, *supra*, and most of them were ingredients of theriaca.

‖ PAULUS ÆGINETA, for example—Lib. IV, Cap. 39, Vol. II, p. 103, Ed. cited p. 624, *supra*—mentions styrax, resin, pitch and mastich among the remedies suitable for this purpose.

¶ Thus PLINY—*Nat. Hist.*, Lib. XXIV, Cap. 22, Vol. VII, p. 3506, Ed. cited p. 771, *supra*—who divides the resins into two species, the dry and the liquid, says that of the latter the product of the larch is employed in coughs and ulcers of the bowels: "Medici liquida raro utuntur, et in ovo fere: e larice propter tussim ulceraque viscerum."

** See GALEN—*De simp. med. temp. ac fac.*, Lib. VIII, Cap. 18, [Ed. Kühn, XII, 135;] DIOSCORIDES—Lib. I, Cap. 90, fol. 38, Ed. cited p. 623, *supra;* and AVICENNA—Lib. II, Tract. 2, Cap. 461, Vol. I, p. 354, Ed. cited p. 632, *supra.*

†† The balsams of Peru and Tolu found their way to Europe during the 16th century: see the *Pharmacographia*, p. 177, Ed. cited p. 703, *supra.*

‡‡ DEGNER—Cap. V, § 24, p. 279, *op. cit.*, p. 625, *supra*—names in this connection oil of amber, balsam of Peru, turpentine and certain "resinous gums," *e. g.*, olibanum, myrrh, mastich, amber and the like: see also, on their use in the fœtid ulcers of chronic cases, Cap. III, § 81, p. 201.

Among the modern physicians who have lauded the employment of balsamic remedies for this purpose I may particularly mention Savignac,* who, however, is by no means alone in this matter. The *compound tincture of benzoin*, which Ellis (1856) recommended in chronic dysentery,† contains, besides benzoin, styrax and the balsam of Tolu as well as aloes, and has enjoyed a certain share of popularity. It is, however, very doubtful whether the balsams exert any particular influence on the intestinal ulcers; certainly they are not more efficient in this way than the oil of turpentine, and the question whether they may not possibly prove beneficial in consequence of the diuretic action of the benzoic acid they contain is one for the solution of which the evidence is as yet insufficient.‡

The *balsam of copaiba*, which Piso and Marcgrave (1648) reported was employed by the Brazilians in diarrhœa and dysentery,§ was again brought forward at the commencement of the present century by Pemberton, who recommended it in the later stages of acute dysentery as well as in chronic cases. It has since been employed with alleged advantage in one or both of these conditions by Armstrong, Woolrich, Pearson, Cheyne, Eberle, La Roche, Robarts, Hatheway and others, while Bampfield was unsuccessful in the trials he made of it.‖ Its use for this purpose was, however, seldom if ever resorted to during our civil war,¶ and I believe at the present time may be regarded as obsolete. The nauseous character of the drug, and a consideration of the readiness with which it irritates even the healthy intestine, when administered, as it has been so freely, for diseases of other organs, will probably discourage any attempt to revive this disagreeble practice.

Greater popularity has been enjoyed by the *oil of turpentine* in the treatment of the fluxes. We begin to hear of the medicinal use of this oil in the latter part of the seventeenth century. It was believed to be possessed of the virtues of turpentine in a more concentrated form, and was employed in the diseases for which that drug was then commonly given, such as catarrhs, phthisis and other affections of the lungs, calculous and other disorders of the kidneys, gonorrhœa and leucorrhœa. It was regarded as eminently heating, aperient, diuretic and antiseptic; but the inconveniences resulting from the administration of excessive doses appear to have limited its employment and called forth grave warnings from Hoffmann and Boerhaave, so that according to Murray (1776) it was very rarely used

---

* SAVIGNAC—p. 411, *op. cit.*, p. 620, *supra*.

† R. W. ELLIS—*On the treatment of chronic dysentery*, The Lancet, 1856, Vol. II, p. 221. It is also classed by CAMPBELL—Vol. XIV, p. 152, *op. cit.*, note ‡, p. 402, *supra*—among the remedies which he calls "rationally specific" in dysentery, viz: "benzoin, balsam copaiba, creosote, turpentine and the like." He cites ELLIS in commendation of the compound tincture of benzoin, and mentions having used it successfully "in a single case."

‡ See, on the subject of the physiological action of benzoic acid, H. C. WOOD—p. 504, *op. cit.*, p. 675, *supra*—and the authorities cited by him.

§ PISO—Lib. IV, Cap. 4, p. 57, *op. cit.*, p. 692, *supra:* "Pectori, ad stomachum languidum, ventri ad colicos frigidos cruciatus, illitum conducit: guttulæ aliquot convenienter exhibitæ per os, robur addunt viscoribus, illisque tonum reddunt: fluxiones muliebres, cursus ventris et gonorrhœas quoque sistunt. In anum per clysteres, in penem per syringam cum saccharo ex aqua plantaginis, vel oleo rosarum dissolutum, adversus eadem mala prospero successu injicitur." G. MARCGRAVE, (de Liebstad,)—*Hist. rerum naturalium Brasiliæ*, (bound up with the last cited work,) Lib. III, Cap. 17, p. 131: "Nervis apprime amicum est: tres vel quatuor guttulæ in ovo sorbili bis vel ter mane sumtæ, dysenteriam vel alios fluxus ventris sistunt et curant."

‖ PEMBERTON—Chap. VIII, p. 145, Ed. cited p. 344, *supra*—used internally a mixture containing copaiba in acute dysentery after "the griping pain had in some degree subsided," and also employed it after the disease "put on the form of chronic diarrhœa." He also in both classes of cases used enemata of balsam of copaiba and starch water. J. ARMSTRONG—*Facts, Observations, and Practical Illustrations*, &c., (1813,) Amer. Ed., Hartford, 1823—article on "Balsam of Copaiva," p. 9—recommended it especially in chronic dysentery as "a suitable laxative, and also a salutary stimulus to the ulcers themselves." WOOLRICH is stated by MCGRIGOR—p. 434, *op. cit.*, p. 612, *supra*—to have used a mixture of balsam of copaiba (in gum Arabic with infusion of calumba) in chronic dysenteries during the Peninsula campaign, and with "great benefit." PEARSON is said by BAMPFIELD—*loc. cit.*, *infra*—to have cured an obstinate case with it. CHEYNE—p. 45, *op. cit.*, p. 686, *supra*—used "the capivi mixture" in acute dysentery, after venesection, calomel and opium. EBERLE—Vol. I, p. 246, Ed. cited p. 778, *supra*—remarked: "In chronic dysentery, balsam copaiva frequently does excellent service." R. LA ROCHE—*Obs. on the use of the balsam of copaiba in diseases of the mucous membrane of the intestinal canal*, The Eclectic Jour. of Med., Vol. II, 1837-8, p. 408—thought it "as serviceable in the secondary stages of acute dysentery as in the chronic form"—p. 414. H. ROBARTS—*Case of suspected ovarian disease*, &c., *with remarks*, The Lancet, 1839-40, Vol. I, p. 569—commended it in "chronic gastro-enteritis." O. P. HATHEWAY—*On the treatment of dysentery with acetate of lead and balsam of copaiba*, The New York Jour. of Med., Vol. XI, 1853, p. 56—recommended it even in acute cases: "Again: we have another excellent remedy, I was about to say a specific, in balsam copaiba." See also CAMPBELL—*loc. cit.*, note †, *supra*—and BAMPFIELD—p. 209, *op. cit.*, p. 682, *supra*.

¶ And yet it was commended by GEORGE B. WOOD—Vol. I, p. 722, *op. cit.*, p. 671, *supra*—in the same class of cases in which he employed the oil of turpentine; and in the tract of STILLÉ—p. 379, *op. cit.*, p. 650, *supra*—who, speaking of the medicaments suitable in chronic dysentery, remarks: "Among remedies of this kind, balsam of copaiva is one of the most valuable."

by the physicians of his time.* It is stated by Rush that oil of turpentine was successfully employed in Philadelphia by Physick, during the yellow fever of 1805, to arrest the hæmorrhagic vomiting characteristic of that disease.† This circumstance induced Chapman to try it in gastritis, and by analogy in enteritis and dysentery: his views on this subject were published in 1819.‡ In 1821 Copland reported that he had employed it with success in several cases of chronic dysentery, and also recommended its use in the chronic diarrhœa of children.§ The manner in which Cheyne combined it with purgative doses of castor oil in the treatment of dysentery has already been referred to.‖

The use of this remedy in the fluxes never, however, enjoyed the reputation either in England or on the Continent which it subsequently obtained in the United States. The well known views of George B. Wood as to its utility in typhoid fever were extended by him to dysentery and the fluxes generally. He taught that whenever the tongue became smooth and dry, in acute or chronic diarrhœa or dysentery, the oil of turpentine was indicated, and acted both as a stimulant and local alterative, the latter property proving especially beneficial in case of the existence of intestinal ulceration.¶ These teachings, like those of this distinguished professor with regard to the use of the oil of turpentine in typhoid fever, were widely adopted in the United States; but the application of the remedy was by no means always limited to the special conditions he had indicated, and the opinion arose in

* The distilled oil of turpentine makes its first appearance in medical literature during the latter part of the seventeenth century. I find in the Augsburg Pharmacopœia of 1684, p. 311, directions for preparing it under the title oleum terebinthinæ, with the statement that the white oil that comes over first is popularly called spirits of turpentine, "quod spiritus nomine vulgo donatur." The essay of JAMES YOUNG—*Triumphal car of turpentine*, London, 1679—I regret to say is not in our library; (I cite from BOERHAAVE—*loc. cit., infra.)* SCHRŒDER is cited by MANGETUS—T. II. p. 965, *op. cit.*, p. 736, *supra*—as saying of the spirits of turpentine: "Spiritus calfacit, siccat, attenuat, urinam ciet, tartaream mucilaginem resolvit. Hinc confert in tussi, aliisque pulmonum affectibus tartareis, in lienis et uteri obstructione, in calculo renum et vesicæ, in stranguria, gonorrhœa virulenta, ulceribus penis ex lue venerea. N. Urina odorem violaceum conciliat." JAMES—T. III, Art. *Terebinthus*, *op. cit.*, p. 690, *supra*—writes: "Turpentine distil'd, or oil of turpentine, is next to oil of balsam, or a little hotter; and is of service in all cold diseases, especially of the nerves. The distil'd oil of turpentine, taken inwardly, is of singular efficacy in nephritic pains." HOFFMANN—*Diss. de terebinthina*, (1699,) Supplementum. Pars Prima, p. 746, Ed. cited p. 681, *supra*—counselled caution in its use, especially if the patient be constipated or plethoric. BOERHAAVE—T. II, p. 95, *op. cit.*, p. 706, *supra*—wrote of this oil: "When used internally, it also proves aperitive, heating, sudorific, and diuretic, communicating a quick smell of violets to the urine;" and adds: "It must however be used with caution, because if taken too largely it affects the head, occasioning heat and pain therein, and also proves violently diuretic, and occasions an effusion of the liquor of the prostate glands and the semen, and, therefore, if used with moderation, it excites venery." He also insists upon the antiseptic virtues of this oil; bodies plunged into it "whilst contained in glasses, are preserved perfectly uncorrupted." Turpentine itself, as well as the balsams, had long enjoyed deservedly the reputation of being antiseptic. Thus FERNELIUS—*Therapeut. universalis*, Lib. V, Cap. 25, p. 271, *op. cit.*, p. 679, *supra*—wrote: "Terebinthina calefacit, mollit, discutit, terget, expurgat: viscerum omnium, maximeque renum, obstructiones tollit, et angustos meatus aperit, urinam ciet, putredinem cohibet." Indeed, the use made of various balsams and terebinthinates in embalming shows how old the knowledge of this property was. MURRAY—T. I, p. 20, *op. cit.*, p. 752, *supra*—wrote of the oil of turpentine: "Interne rarissime usurpatur, et cautionem requirit."

† BENJ. RUSH—*An account of the bilious yellow fever, as it appeared in Philadelphia, in the year* 1805, Med, Inquiries and Obs., Vol. IV, 4th Ed., Philadelphia, 1815, p. 96: "The only new medicine that the experience of this year suggested in this disease, was for one of its most distressing and dangerous symptoms, that is, the vomiting which occurs in its second stage. Dr. Physick discovered, that ten drops of the spirit of turpentine, given every two hours, in a little molasses, or syrup, or sweet oil, effectually checked it in several instances, in patients who afterwards recovered." This would seem to fix the date, yet STILLÉ—Vol. I, p. 759, *op. cit.*, p. 711, *supra*—citing the same passage, writes: "It was first used by Dr. Physick of Philadelphia in 1798." I know not where he got this date; certainly RUSH—Vol. cited, p. 39 *et seq.*—does not in any way allude to this treatment in his account of the epidemic of 1798.

‡ N. CHAPMAN—*Discourses on the Elements of Ther. and Mat. Med.*. Vol. II, p. 170, Philadelphia, 1819—after mentioning PHYSICK'S practice, writes: "The stomach in yellow fever, at the period the turpentine is prescribed, is in the state of inflammation approaching gangrene, and by the arrestation of which, I presume, it operates so advantageously. Exactly under similar circumstances of peritoneal inflammation, which partakes much of the nature of gastritis, I have now for a number of years prescribed the medicine, and with unequivocal advantage. Nor do I believe it to be less suited, though my experience in this respect is narrower, to the same state in enteritis, whatever may be the cause, whether induced in the ordinary way, or by acrid poisons, or associated, as it sometimes is, with dysentery." He adds: "In the low fevers, when other diffusible stimuli are given, much may be expected from turpentine. It was a common remedy with me in the sinking condition of our winter epidemic, and I had, in some instances, much reason to be satisfied with its effects." This view was quite in accordance with the teachings of CULLEN, who held—Vol. II, p. 184, *op. cit.*, p. 740, *supra*—that the oil of turpentine "seems to be a very diffusible stimulus." In the fourth edition of the work just cited—Vol. II, 1825, p. 134—CHAPMAN praises the use of the oil of turpentine also in cholera infantum, and adds: "In chronic diarrhœa, with such discharges as denote the mucous coat of the intestines to be chiefly affected, it is an incomparable remedy."

§ JAMES COPLAND—*A memoir on the employment of terebinthinous remedies in disease*, The London Med. and Phys. Jour., Vol. XLVI, 1821, p. 196.

‖ CHEYNE—see p. 709, *supra*.

¶ See, for the views of WOOD on the use of turpentine in typhoid fever, his essay *On the use of the oil of turpentine, in a particular condition of fevers*, The North American Med. and Surg. Jour., Vol. I, 1826, p. 272; also the various editions of his treatises on the *Practice of Medicine*, and on *Therapeutics and Pharmacology*. A discussion of this subject would be out of place here. For his teachings with regard to its use in dysentery, see Vol. I, p. 575, of the first edition of his *Practice*—cited p. 691, *supra*—and the corresponding passages in subsequent editions. I cite the following striking paragraph from his *Therapeutics and Pharmacology*, 2d Ed., Philadelphia, 1860, Vol. I, p. 566: "*Dysentery and Diarrhœa.* Whenever, in the course of these complaints, whether acute or chronic, the tongue exhibits a smooth surface, as if deprived of its papillary structure, and at the same time becomes perfectly dry. I always unhesitatingly employ the oil of turpentine, believing that this aridity indicates a deficiency of the vital forces, which calls for the stimulating property of the oil, while the probable existence of ulcers in the bowels requires its alterative action."

certain quarters that it might be advantageously employed as an alterative to the mucous membrane, or almost as a specific in all stages of dysentery; a view well illustrated by the papers of Long and Campbell.*

Accordingly, during our civil war the oil of turpentine was pretty extensively employed in the treatment of the fluxes, both in combination with purgative doses of castor oil and in emulsion, with a view to its stimulant and alleged alterative effect.† A few expressions of favorable opinion with regard to it will be found in the reports, but I have been unable to collect any detailed evidence that it ever manifested any decided power in checking or beneficially modifying the progress of these disorders. It frequently irritated the stomach and provoked nausea and vomiting; often the number of the discharges was increased under its use; and even when it was tolerated it was only too common for the grave ulcerative cases, for which it was supposed to be especially suited, as well as those in which no ulcers existed, to terminate fatally in spite of its employment, as is strikingly illustrated by a number of the cases recorded in a previous part of this chapter.‡ I know of no reason for believing that the relative mortality of those thus treated was any less than that of similar cases treated in other ways; nor have I been able to gather, from modern investigation into the physiological action of the oil of turpentine, any evidence in support of the view that it is really serviceable as a local alterative in either inflamed or ulcerated conditions of the intestinal mucous membrane.

The latter observation may be made with regard to all the other drugs belonging to the group under consideration. The belief that they possess these virtues is so venerable, and has been shared by so many reputable practitioners in ancient and modern times, that it would be bold, and perhaps erroneous, to declare that it is entirely unfounded; yet candor compels the statement that it is unsupported by scientific evidence. The other belief, which has become more and more universal in modern times, that the oil of turpentine is a cardiac and nervous stimulant, undoubtedly rests upon a sounder foundation; but very little is positively known of the manner in which it acts,§ and the clinical testimony in our possession by no means fixes accurately the limits of its usefulness. I suppose no one would seriously propose it as a substitute for alcohol in low febrile conditions, and I know of no clinical evidence which clearly proves that by employing it in addition to alcohol better results can be obtained than by alcohol alone.

Camphor, unknown to Greek and Roman medicine, is described by Serapion, Avicenna and other Arabian writers, who classed it among the cold and dry remedies, believed it to possess a certain degree of astringency, and regarded it therefore as a useful addition to the

---

* JOHN LONG—*Turpentine in dysentery*, St. Louis Med. and Surg. Jour., Vol. X, 1852, p. 209. CAMPBELL—Vol. XIV, 1858, p. 160 *et seq.*, *op. cit.*, p. 402, *supra:* "The remedy, which we prefer to all others, as the safest, the best, and most efficient in its operation upon the affections of the mucous tissue in general; and which, besides being of the most general applicability in the affections of this tissue—is pre-eminently to be chosen as the agent for the treatment of dysentery. This remedy is TURPENTINE." He gives the oil of turpentine in emulsion in combination with compound spirit of lavender, camphor water, bicarbonate of soda and castor oil; attaching great importance to the latter ingredient both as a laxative and a means of "anointing the interior surface of the intestinal canal"—p. 165. In this place I may conveniently refer also to the paper of J. W. MOORMAN—*Oleum Erigerontis Canadensis as a remedy in hemorrhage, diarrhœa and dysentery*, The Amer. Jour. of the Med. Sci., Vol. L, 1865, p. 396.

† As to the employment of oil of turpentine in combination with castor oil, see p. 709, *supra*. With regard to its use in small doses, see the reports in Section II of STORROW—p. 43, *supra;* SCHÜSSLER—p. 44; COUES—p. 64; BROWN—p. 81; WALTON—p. 88; COOPER and COOK—p. 93. This use of the oil was not mentioned in the handbook of TRIPLER—*op. cit.*, p. 691, *supra*—or the tract of STILLÉ—*op. cit.*, p. 659, *supra;* nevertheless I have reason to believe, both from observation and from conversation with medical officers, that it was resorted to more generally than appears from the reports.

‡ As illustrations, I may refer to cases 178, 188, 194, 219, 232, 234, 235, 241, 242, 243, 244, 245, 246, 247, 254, 307, 425, 468, 496, 518, 522, 536, 540, 547, 570, 589, 590, 591, 609, 611, 614, 639, 672, 689, 696, 784, 788, 789, 797, 819, 855 and 857.

§ For summary accounts of the present condition of our knowledge on this subject, see H. C. WOOD—p. 126, *op. cit.*, p. 675, *supra*—and BUCHHEIM—*loc. cit.*, p. 815, *supra*. Among the special essays I have examined with interest, I may mention those of HOPPE—*Die Nervenwirkungen des Terpenthinöls*, Jour. für Pharmacodynamik, Toxicologie u. Ther., Bd. I, 1856, S. 105 *et seq.;* LÉON CRUCIS—*Action physiologique et morbide de la térébenthine et de quelques autres hydrocarbures*, Paris Thesis, No. 155, 1874; and C. BINZ—*Ueber einige Wirkungen ätherischer Oele*, Archiv für experimentelle Path. u. Pharm., Bd. V, 1876, S. 109, and Bd. VIII, 1877-8, S. 50.

medicines prescribed in the alvine fluxes, and especially in such as proceed from an excess of bile.* These opinions prevailed through the middle ages. As late as the middle of the sixteenth century Fernelius still taught, like the Arabians, that camphor is cold and dry in the third degree;† and although Ambroise Paré employed it in gangrene, and recommended that it should be added to the alexipharmics administered in the plague, he expressly stated that he did so on account of its refrigerating properties.‡ Subsequently it acquired the reputation of being itself an alexipharmic, and of possessing the power of resisting putrefaction in a wonderful manner.§ Accordingly it was employed in the plague and in pestilential fevers by Mindererus, Diemerbroeck, Ettmüller, Hoffmann, Huxham and others.‖

Meanwhile, early in the seventeenth century, the Arabian dictum that camphor is a cooling remedy became a subject of controversy, and the opinions of those who held that it is really possessed of calefacient virtues temporarily secured the victory.¶ But this change of opinion does not appear to have modified materially the frequency with which it was administered both in putrid fevers and in the fluxes. Attention was directed, however, more and more to its antiseptic virtues, the belief in which was greatly strengthened by the experiments made by Pringle about the middle of the last century;** while at a later period the old controversy as to whether it is heating or refrigerant was revived by Cullen, who, however, put the question in other words, and asked whether it is stimulant or sedative, warmly advocating the latter view.†† The discussion of this question has been continued almost to the present day; but it is unnecessary to trace its progress here, or to sketch the history of the modern use of the drug in the low forms of fever. Its reputation in the latter group of diseases has given it some vogue in adynamic dysenteries and those complicated

* SERAPION—Cap. 334. fol. 177, *op. cit.*, p. 806, *supra:* "Et camphora quidem est frigida et sicca in tertio gradu, confert calefactis, et patientibus fodam cholericam, quando odoratur simplex, aut cum aqua rosacea, aut sandalis confectis, et odor camphoræ abscindit desiderium coitus. Sed potio ipsius est fortioris operationis, et quando miscetur ex ea quantitas pauca cum medicinis stringentibus fluxum ventris cholericum, fit ejus operatio melior." Moreover, camphor restrains undue warmth of the cerebrum, and thus produces sleep, checks hæmorrhages from the nose, may be advantageously combined with subtances used for fumigation, and either by its vapor or taken internally is useful in all diseases proceeding from the hot temperament. But as a consequence of these qualities, if it be taken to excess, it chills the kidneys and bladder, coagulates the sperm and generates frigid diseases, especially in cold climates: moreover, its use causes the hair to turn gray. AVICENNA—Lib. II, Tract. 2. Cap. 133, p. 291, Ed. cited p. 632, *supra*—held substantially the same views: "Abscindit coitum, et generat lapidem renum, et vesicæ, et constringit fluxum ventris cholericum." He also speaks favorably of its use in fevers. The belief of SERAPION that the mere odor of camphor destroyed the sexual appetite is perpetuated in the old rhyme: "Camphora per nares castrat odore mares:" see DALE—p. 300, *op. cit.*, p. 729, *supra*.

† FERNELIUS—*Meth. Med.*, Lib. VI, Cap. 1, p. 275, *op. cit.*, p. 679, *supra:* "Caphura frigida sicca gradu tertio, lacryma indicæ arboris, tenuium partium, acris et odora repellit et facile penetrat: phlegmonas et erysipelata refrigerando mire juvat, ad gonorrhœam et albas vulvæ fluxiones efficax, cum succino e conveniente liquore hausta."

‡ AMBROISE PARÉ—Lib. XXIV, *De la peste*, Malgaigne's Ed. of Œuvres, T. III, Paris, 1841, Chap. 24, p. 406. After speaking of the use of theriaca and the antidote of MITHRIDATES in the plague, he writes: "Vray est que quand la fiéure est fort grande, il les faut mesler auec choses refrigerantes, comme trochisques de camphre (lequel mesme preserue le corps de pourriture, et pource est commodément meslé és antidotes contre la peste)," &c.

§ See, for example, FAB. HILDANUS—*De gangræna et sphacelo*, 1593; I cite Opera, Frankfort, 1646, p. 787: "Camphora enim inter fortissima alexiteria non immerito a viris doctis numeratur: putredini enim mirum in modum resistit. Quapropter non solum vapores, qui ex corrupto et putrefacto membro versus cor ascendunt, repellit; verum etiam maximum illum calorem internarum partium temperat." It will be seen that he still holds to the notion that it is a cooling remedy. I may add that FERNELIUS—Lib. V, Cap. 21, p. 266, *op. cit.*, note †, *supra*—had previously written: "Caphura malignos vapores, præsertim calidos, extinguit, ab hisque ortam sensuum exolationem reparat."

‖ R. MINDERERUS—*De Pestilentia*, Cap. 15, p. 197 of the copy in our library, which is without date, but which I suppose to be the Augsburg Ed. of 1619: "Proindeque camphoram inter fortissima ac validissima pestis alexiteria non immerito reposuerim sive frigida hæc sit sive calida." I. DE DIEMERBROECK—*De Peste*, Lib. III, Cap. 5, Arnheim, 1646, p. 162 *et seq.* In the annotations to this chapter—p. 170—he repeats the praises of MINDERERUS and others. ETTMÜLLER—*Institut. Med. Therapeutice*, Pars I. Cap. 17, T. I, p. 227, Ed. cited p. 647, *supra*—in speaking of the treatment of the plague, writes: "Præterea subinde laudavi camphoram, quæ certe in peste curanda omnibus præfertur." F. HOFFMANN—*Diss. med. de camphoræ usu interno securissimo et præstantissimo*, 1714; I cite Opera, T. VI, p. 63, Ed. cited p. 681, *supra:* "Quicunque itaque malignos contagiosos corpore arcere vult morbos, is vel ipsum putridum miasma, vel quod ab ipso corruptum fuit, ex corporis nostri sphæra propellere omni studio atque opera nitatur. Nihil vero ad hoc præstandum aptius est camphora." See also J. HUXHAM—*De febribus*, 1739, T. II, p. 116, *op. cit.*, p. 659, *supra*.

¶ See, on this subject, SENNERTUS—Lib. IV, Part 2, Sect. 3, Cap. 5, Vol. III, p. 581, *op. cit.*, p. 645, *supra—Quæstio. An camphora sit frigida vel calida, et an Venerem exstinguat.* It has been held to be frigid, he says, because it is useful in pains of the head, inflammation of the eyes and the like, and because it extinguishes the sexual desire. But others believed it to be heating, because it excites inflammations and is of a thin, penetrating substance and acrid taste. He himself regards the latter opinion as most in accord with the truth. The same view of the question was taken by J. A. WEDEL, as cited by MANGETUS—T. I, p. 458, *op. cit.*, p. 736, *supra*—and DALE—p. 300, *op. cit.*, p. 729, *supra*.

** In these experiments, read before the Royal Society, June 28, 1750—see note *, p. 803, *supra*—PRINGLE found that "two grains of camphire, mixed with water, preserved flesh better than sixty grains of sea-salt:" see Appendix, p. xii, *op. cit.*, p. 640, *supra*. He used this drug both in inflammatory fevers—p. 129, *op. cit.*—and in hospital fever—pp. 310 and 316; but appears to have made no use of it in either diarrhœa or dysentery.

†† CULLEN—Vol. II, p. 292, *op. cit.*, p. 740, *supra:* "The controversy has been commonly brought into the single question, Whether camphire be a heating or a cooling medicine with respect to the human body? or, as I would put it in other words, Whether it is a stimulant or a sedative power?"

with typhoid fever. It has been recommended in these conditions by Tissot, Zimmermann, Birnstiel, Schumacher, Hauff and others; while Sponitzer and Mende regarded it as useful also in the simple catarrhal forms of the disease.* Annesley held it to be a valuable adjuvant in the treatment of tropical dysentery. He believed that it possessed the power of determining to the skin and of diminishing vascular action, while at the same time it controlled the tendency to spasm without retarding the operation of purgative medicines.† On the other hand, Naumann reported that in nervous putrid dysentery the effects of camphor and opium seldom corresponded to his expectations, and Fouquet declared that he was unable to discover a single reason in favor of its employment either in the so called putrid or any other dysenteries.‡

Many of the best modern writers on dysentery preserve a contemptuous silence with regard to the use of this drug; but it must be admitted that in certain quarters the sanguine views of Annesley still survive. Nevertheless, for the most part in modern, as in ancient, times camphor has been regarded rather as a useful addition to the more powerful drugs usually employed in the treatment of dysentery or other forms of flux than as a remedy that can be relied upon alone. It has been added to the most diverse anodyne and astringent mixtures and pills, and has especially been employed in combination with opium. Pills of camphor and opium have had considerable popularity in the treatment of simple diarrhœa. Such pills, containing each two grains of camphor and one of opium, figured in the medical supply table of our army during the civil war, and nearly half a million dozen of them were purchased for issue.§

Modern investigation into the physiological action of this drug seems to indicate that it resembles in many respects that of oil of turpentine and the volatile aromatic oils.‖ Like them, it is a local irritant capable in excessive doses of producing gastritis, though less active in this direction than most of the essential oils; like them, in moderate doses it appears to stimulate the vascular and nervous systems, while poisonous quantities produce vertigo, headache, delirium, epileptiform convulsions, unconsciousness and death.¶ The question of its real utility in the fluxes is one that still requires further study. Some

* TISSOT—*loc. cit.*, note ¶, p. 797, *supra*. ZIMMERMANN—Cap. X, S. 476, *op. cit.*, p. 648, *supra:* "Nach der Peruvianischen Rinde oder in dem gleichen Range mit derselben, kann man sich in der bösartigen Ruhr zur Emporhebung der Kräfte des Campfers bedienen." It may be very conveniently joined to the extract of bark, and even with ipecacuanha. BIRNSTIEL—Sect. VII, S. 300, *op. cit.*, p. 770, *supra*—commended it in dysentery complicated with putrid fever; F. SCHUMACHER—*Beyträge zur Nosogenie und Nosologie der Ruhr*, Frankfort, 1813, S. 186—in the typhous form of dysentery; and HAUFF—S. 453, *op. cit.*, p. 534, *supra*—in secondary typhous and nervous paralytic dysentery. SPONITZER—*Von den Wirkungen des Camphors in verschiedenen Krankheiten und den Cautelen bey der Anwendung desselben*, Hufeland's Jour., Bd. V, St. 3, 1798, S. 546—found it even useful in simple rheumatic (catarrhal) dysentery, but especially in putrid cases in which there was great loss of strength. In the Luxemburg epidemic of 1793 he gave with advantage two to three grains every three hours, often combined with Sydenham's laudanum and Peruvian bark. L. MENDE—*Epidemische Gelbsucht in den Jahren* 1807 *und* 1808, same Jour., Bd. XXXI, St. 8, 1810, S. 88—gave it in simple rheumatic dysentery and in cases complicated with intermittent fever, and regarded it as one of the chief means of cure.

† ANNESLEY—Vol. II, p. 297, *op. cit.*, p. 621, *supra*—remarks that he "generally found it most useful in conjunction with other remedies, given in repeated doses, and in combination with anodynes and laxatives." He thought the dose should not exceed two or three grains early in the disease; but that it might be increased to five or six in the advanced stages.

‡ NAUMANN—Bd. IV, Abth. 2, S. 97, *op. cit.*, p. 645, *supra*. FOUQUET—p. 196, *op. cit.*, p. 753, *supra*.

§ According to the report of Surgeon SPENCER—cited note †, p. 708, *supra*—the number of these pills purchased for issue was 448,895 dozen. As each consisted of two grains of camphor and one of opium, the total quantity of gum camphor contained in them was 1,539 lbs., (avoirdupois.) To this must be added the quantity of paregoric mentioned in note ‡, p. 743, *supra*, viz, 993,311 ounces, which contained about 177 lbs. of camphor. Surgeon SPENCER furthermore gives the quantity of gum camphor purchased in substance as 924.184 ounces, or 57,761 lbs., (avoirdupois;) of course a large part of this supply was employed in making soap liniment and for other external uses. It will be observed that the total supply of gum camphor amounted to very nearly 30 tons, (of 2,000 lbs. each.) Surely if the old Arabian dream were true, the quantity was sufficient to have at least preserved the chastity of the army, even if its fluxes were not cured.

‖ See, for an account of these investigations, the work of the HUSEMANNS—S. 975, *op. cit.*, p. 766, *supra;* H. C. WOOD—p. 192, *op. cit.*, p. 675, *supra;* and BUCHHEIM—S. 561, *op. cit.*, p. 746, *supra*. Among the special papers I have examined with interest I may mention those of A. MALEWSKI—*Quædam de camphora, carbonco sesquichlorato, cumarino vanillaque meletemata*, Diss. Inaug., Dorpat, 1855; O. HEUBNER—*Ueber die Wirkung des Kamphers auf die Leistung des Froschherzens*, Archiv der Heilkunde, 1870, S. 334; E. ZIEGLER—*Ueber das Verhalten des Camphereymols im thierischen Organismus*, Archiv für experimentelle Path. und Pharm., Bd. I, 1873, S. 65, (which treats of the chemical changes this substance undergoes in the organism;) and the two papers of BINZ, cited note §, p. 818, *supra*.

¶ On the toxic action of camphor, see, besides the works cited in the last note, ORFILA—T. II, p. 639, *op. cit.*, p. 699, *supra;* TAYLOR—p. 661, *op. cit.*, p. 791, *supra;* and other treatises on toxicology.

excellent recent writers acknowledge that its employment in the adynamic fevers is of doubtful advantage;* and the evidence that it produces any decided benefit in diarrhœa or dysentery is still less conclusive. Certainly I should be unwilling to rely upon it as a stimulant in adynamic dysenteries; and although no doubt the painful cramps that often accompany slight intestinal catarrhs can frequently be allayed by it, it may well be questioned whether it is the best remedy to select for this purpose.

ANTISEPTIC REMEDIES.—In connection with a number of the medicaments hitherto discussed, reference has been made to their supposed virtues as antiseptics capable of arresting the putrefaction of the humors, or as parasiticides acting by compassing the destruction of the imagined living cause of the disease. Calomel, Peruvian bark and quinia, the simple and aromatic bitters, strychnia, the mineral acids, turpentine and camphor are among the principal substances that have been selected with this view. The modern speculation, that the cause of the septic processes that occur in disease is to be sought in the bacteria and other low forms of vegetable life, which develop during their progress, has led to a general revival of therapeutic effort in this direction. Besides the substances already mentioned as having been employed with such views, particular attention has been directed to *carbolic acid*, the employment of which was preceded by favorable reports of the usefulness of *creasote* in diarrhœa and dysentery.† Carbolic acid has been used internally in these diseases by Rothe, Amelung, Thoresen and others,‡ while the *sulphocarbolate of calcium* has been employed by Sansom in the diarrhœa of children for the same purpose.§ Wagner and others have resorted instead to *salicylic acid*,‖ and *chlorine water* has been advocated by Dyes and Schneider.¶

It would be perhaps premature to enter upon a detailed discussion of the question of the propriety of such attempts. I confess, however, I have no confidence whatever in the utility of this mode of medication. I have already endeavored to show** that the facts hitherto brought forward in support of the theory that the fluxes are caused by low vegetable forms are insufficient to demonstrate its truth. It is at best a plausible speculation which the enthusiastic may accept as an article of belief, but the prudent will decline to elevate above the rank of an undemonstrated hypothesis.†† Even if this speculation were proved

* For example, my friend H. C. WOOD—*loc. cit.*, note ‖, last page—writes: "In adynamic fevers it has been very greatly employed, but is of doubtful advantage: still, a good deal of testimony could be adduced in favor of its usefulness in sustaining the system in the low stages of these diseases; and in nervous restlessness occurring at such times it is often very soothing."

† On the use of *creasote* in diarrhœa and dysentery, see the following essays: J. A. MAYES—*Cases of diarrhœa, with emaciation, coming on after weaning, successfully treated with creosote*, Southern Med. and Surg. Jour., Vol. II, 1846, p. 583; and *Application of creosote to the treatment of diarrhœa and dysentery*, same Jour., Vol. III, 1847, p. 147; C. N. SPINKS—*On the use of creosote in the treatment of diarrhœa*. The London Med. Gaz., Vol. IX, 1849, p. 254; W. B. KESTEVEN—*Beneficial effects of creosote in the treatment of diarrhœa*, same Jour., Vol. XII, 1851, p. 235; W. H. MCMATH—*Creosote in dysentery, with cases*, Southern Med. and Surg. Jour., Vol. XIII, 1857, p. 579; J. W. BROWN—*Creasote in dysentery*, Nashville Jour. of Med. and Surg., Vol. XIII, 1857, p. 306; J. B. PAYNE—*An essay on the ætiology, pathology, and treatment of epidemic dysentery*, The New Orleans Med. and Surg. Jour., Vol. XV, 1858, p. 93; J. JOHNSON—*Treatment of diarrhœa*, The Med. Times and Gaz., 1867, Vol. II, p. 138; and G. B. LARTIGUE—*Creasote in cholera*, Philadelphia Med. Times, Vol. II, 1871-2, p. 8. Here, too, I may refer to the use of *naphtha* in diarrhœa by J. C. LAVIROTTE—*Emploi de l'huile de napthe dans la diarrhée*, Gaz. des Hôpitaux, 1849, p. 46.

‡ On the internal use of *carbolic acid* in diarrhœa and dysentery, see S. O. HABERSHON—*Functional disease of the colon*, &c., The Lancet, 1868, Vol. I, p. 7; C. G. ROTHE—*Carbolsäure innerlich gegen Diarrhœn und Cholera*, Berliner klin. Wochenschrift, 1871, S. 527—and *Die Carbolsäure in der Medicin*, Berlin, 1875, S. 37 *et seq.*; AMELUNG—*Zur Behandlung der Dysenterie*, Berliner klin. Wochenschrift, 1873, S. 125; and N. W. THORESEN—*Zur therapeutischen Verwendung der Carbolsäure*, Norsk Mag., Vol., IX, 1875, S. 449; I cite from Schmidt's Jahrb., Bd. CLXIX, 1876, S. 122.

** See pp. 278 *et seq.*, 367 *et seq.* and 643 *et seq.*, *supra*.

†† As I write this paragraph I have before me a paper by Prof. JOHN TYNDALL—*Virchow and evolution*, The Popular Science Monthly, January, 1879, p. 288 *et seq.*—in which that agreeable and usually instructive lecturer fiercely attacks the conservative views expressed by VIRCHOW in his address at Munich, September 22, 1877—*Die Freiheit der Wissenschaft im modernen Staat*, Berlin, 1877, S. 15 *et seq.*—on the question of contagium animatum. Professor TYNDALL in this century, like DES CARTES in the seventeenth, appears to imagine that his acknowledged meritorious attainments in certain branches of physical science justify him in expressing quite positive opinions on almost any subject, religious or scientific, he may care to discuss, without

to be true, it still remains to be shown that any of these substances can be introduced into the blood in such quantities as to prevent the experimental or pathological development of the low forms in question, or even that they can be administered without peril to life in sufficient quantities to destroy the vitality of the similar forms that habitually swarm in the lower part of the alimentary canals of healthy individuals.*

OTHER MODES OF TREATMENT.—It remains to refer briefly to a few other remedies which have enjoyed popularity in the treatment of the fluxes. Here may be mentioned *arnica*, which was lauded as a remedy in dysentery by Collin, Stoll, Birnstiel and Richter during the last century, and which, at a comparatively recent period, Savignac has suggested is perhaps worthy of a place in the therapeutics of that disease.† It is, however, seldom employed by modern physicians for this purpose, and the little that is really known of its mode of action is hardly favorable to any attempt to revive its use.‡

Ergot, in powder or fluid extract, as well as the extract which Bonjean improperly called ergotine, has been used to a limited extent in dysentery and chronic fluxes. Successful results had been reported by Gervis, Rillet and Lombard, Fontayral and others; but it was especially the success claimed for it by Massolaz in the fluxes of the Sardinian army during the Crimean war which brought it into temporary repute.§ His observations

---

the necessity for any particular investigation of it. In this matter, although I think he is rather too liberal in his concessions to the modern disciples of the contagium animatum, I respect the opinions of VIRCHOW as the ripe utterances of a great intellect devoted now for many years to the study of disease; but I can attach no more importance to those of TYNDALL than to his speculations on any other subject not embraced in his own particular field of personal investigation. Indeed, I do not hesitate to express the opinion that, in the actual condition of scientific inquiry on the subject, the reception of the doctrine of contagium animatum as a general theory of epidemic and contagious diseases requires on the part of the believer an act of faith quite as great as that which Professor TYNDALL explains in the same paper—p. 271—he has found it so impossible to exercise with regard to "the eternal Sonship of Christ," "the resurrection of the body," and other doctrines of the Christian religion.

* In this place I may mention the use of *santonin* in Coehin China diarrhœa, a practice suggested by the view of NORMAND—see pp. 372 and 757, *supra*—that the disease is caused by an anguillula: see L. COLIN—*Diarrhée de Cochinchine; guérison par la santonine*, Gaz. Hebd., T. XV, 1878, p. 132. The suggestion is at least consistent with the theory. After the parasiticides, vermifuges!

† According to SPRENGEL—Bd. IV, S. 545, *op. cit.*, p. 346, *supra*—the *arnica montana* was well known to the botanists of the sixteenth century, and was long employed as a popular application to bruises before it was brought into medical use. Probably the earliest account of its virtues, when given internally, is that of J. M. FEHR—*De arnica lapsorum panacea*, Misc. Cur. German., Dec. I, an. 9 et 10, 1678–9, Obs. 2, p. 22—who declares it to possess acrimony and an aromatic virtue, to be diuretic and sudorific, useful in catarrh, asthma, colic, hysterical pains, in slow fevers, &c. It was lauded by H. J. COLLIN—*Obs. circa morbos acutos et chronicos factarum Pars IV*, Vienna, 1773, pp. 5, 79 and 107, *Pars V*, 1775, pp. 132, 209, 263 and 323—whose work, I regret to say, is not in our library. SPRENGEL, from whom I cite the above reference, states in the first edition of his history—Bd. V, Halle, 1803, S. 352—that asthenic diarrhœas and putrid dysenteries were among the diseases for which he employed it: this passage is omitted in the third edition of SPRENGEL'S work. According to STOLL—*Rationis Medendi Pars I*, Vienna, 1788, p. 125—COLLIN used no evacuants in the treatment of dysentery, but relied upon arnica alone. STOLL himself—*Pars II*, p. 369, *op. cit.*—regarded arnica root as possessed of antiseptic virtues, and writes: "Nullum certe medicamentum novi, quod specifici antidysenterici compellationem majori sibi jure possit vendicare." He regarded it as especially useful in the fluxes that so often accompany malignant fevers, in diarrhœas proceeding from debility of the abdominal viscera, and in the colliquative diarrhœas of those laboring under purulent discharges, as well as in dysentery. In camp dysentery it is especially valuable, and will so be recognized by those who manage the sanitary affairs of armies in future times. What a benefit it would be to military medicine if the great antiseptic powers of this medicament were more generally known! In June, 1777, he treated about 20 cases of dysentery successfully by this remedy, an emetic having first been administered—p. 46. He commends it especially in the varieties of dysentery he called *febris biliosa dysenterica* and *febris putrida dysenterica:* in the latter form he gave as much as half a drachm of the powder of the root every two or three hours—*Pars III*, p. 266 *et seq.* Nevertheless in the simple dysenteries of August, 1778, it was injurious—p. 252. As for arnica flowers, they exercise their specific powers chiefly upon the stomach, and are useful especially in putrid fevers of gastric origin—p. 159 *et seq.:* he did not employ them in dysentery. BIRNSTIEL—p. 237, *op. cit.*, p. 770, *supra*—cites with admiration the views of STOLL as to the use of arnica root in dysentery; he himself appears to have preferred—p. 286—an infusion of arnica flowers, to which he added vinegar and syrup of althæa. RICHTER—Bd. I, S. 103, *op. cit.*, p. 731, *supra*—declared that arnica acts in a really wonderful manner in dysentery when the evacuations have an offensive odor and there is great debility. SAVIGNAC—p. 396, *op. cit.*, p. 620, *supra*—writes: "Inscrivons donc, sous toutes réserves, la poudre de racine d'arnica (et non les fleurs, comme le disent certains auteurs) dans le formulaire thérapeutique de la dysentérie."

‡ See, on this subject, the work of the HUSEMANNS—S. 939, *op. cit.*, p. 766, *supra;* H. C. WOOD—p. 157, *op. cit.*, p. 675, *supra;* and BUCHHEIM—S. 578, *op. cit.*, p. 746, *supra*. On account of the volatile oil contained in this plant the last named author treats of it in his "Gruppe des Terpenthinöls." STILLÉ—Vol. I, p. 731, *op. cit.*, p. 711, *supra*—classes arnica among the general stimulants, while H. C. WOOD—*loc. cit.*—regards it as a cardiac sedative, partly from the symptoms in some cases of poisoning, of which, however, he only claims that they "seem in a measure to bear out this view," but chiefly, it would appear, on the basis of the clinical observations of C. C. BALDING—*On the value of tincture of arnica in the treatment of acute pulmonary affections*, The Lancet, 1870, Vol II, p. 885.

§ F. S. GERVIS—*Use of ergot of rye in dysentery*, The Lancet, 1846, Vol. II, p. 39—reports a case with bloody discharges in which he successfully used Battley's solution of ergot with tincture of sesquichloride of iron. According to J. BONJEAN—*Emploi de l'ergotine chez les malades et les blessés de l'armée d'Orient*, Chambéry, 1855, p. 7—the epidemic of typhoid fever in Geneva in 1853 was accompanied by many cases of dysentery in which ergotine was used with success by RILLET and LOMBARD; and that FONTAYRAL (à Eymet) had published in the Jour. des Sci. Med. Pratiques de Montpellier, T. VI, 1854, p. 293, and T. VII, p. 242 *et seq.*, (the volumes are not in our library,) a series of observations on the successful treatment of chronic dysentery by the same medicament. MASSOLAZ—*Emploi de l'ergotine dans la diarrhée épidémique de l'armée Sarde en Orient, pendant l'été de* 1855, Répertoire de Pharmacie, T. XIII, 1856–7, p. 153: see also a brief note on this subject in the report of the proceedings of the Académie des Sci., Aug. 18, 1856, Gaz. Hebd., T. III, 1856, p. 620—used it with alleged success in the chronic diarrhœas of the Sardinian army in the Crimea. He mixed 1 to 2 grammes in 120 grammes of sweetened water, and gave a teaspoonful every half hour. A later work by FONTAYRAL—*Le seigle ergoté et de l'application de l'ergotine à la cure de la dysenterie et de la diarrhée chroniques*, Montpellier, 1858—is not in our library.

suggested its use to Tripler, who obtained success with it in several cases of chronic dysentery, and, although it failed in others, recommended that further trial should be made.* His counsels did not lead to its introduction into military practice during the civil war, but since then a number of favorable notices of its use in diarrhœa and dysentery have appeared in the journals, which, however, have not convinced me of the wisdom of this mode of treatment.† Savignac declares that he employed it a good deal, obtained no great advantages, and ended by renouncing it; yet thinks it may be useful as a hæmostatic in hæmorrhagic cases.‡ This view appears reasonable; but when the nature of the phenomena of ergotism is considered, the impropriety of exhibiting the drug continuously in the chronic fluxes will be apparent.§

The internal use of white *arsenic* in the fluxes, for which Harles so severely blamed the later Greek and Arabian physicians, has been revived in comparatively modern times.‖ The preparation used for this purpose is Fowler's solution. Tripler stated that he had employed it in several cases of chronic dysentery, and always with more benefit than any other remedy he had ever used.¶ His praise induced several of our medical officers to try it during the civil war; some of them reported favorable results, while others were disappointed.** It has since been recommended by Ringer in chronic dyspepsia complicated with diarrhœa, and in other chronic forms of flux.†† I do not doubt that in diarrhœas kept up by the malarial cachexia or complicated by ague the administration of this remedy has frequently been followed by beneficial results;‡‡ and it is possible, though hardly probable, that in other chronic fluxes its use in small doses may occasionally be followed by a beneficial modification of the condition of the intestinal mucous membrane. But the more I consider what is known of the effects of the persistent administration of this powerful drug in other diseases, the more I incline to the opinion that even in fluxes with malarial complication it would be better to rely upon quinia or other suitable medicaments than to invoke the treacherous assistance of a substance so prone to produce serious intestinal irritation. Those who have employed it with a view to its constitutional effects know well how apt it is to produce digestive disturbances and diarrhœa, even in those whose intestines are healthy. Is it at all probable that these accidents are less likely to occur when the intestinal mucous membrane is already inflamed or ulcerated?

Considerable interest was aroused in 1864 by the reported success of Acting Assistant Surgeon H. F. Gilbert in treating chronic fluxes with *bromine* and *iodine* at the Rock Island

---

VIII, 1871, p. 610; A. PALMBERG—*Ueber die Wirkung des Secale cornutum bei chronischer Diarrhöe*, Finska läkaresällskapets handlingar, XIII, 2. p. 75, 1871; I cite from Schmidt's Jahrb., Bd. CLII, Jahrg. 1871, S. 20; C. HANDFIELD JONES—*Two cases of chronic dysentery, with remarks*, The Med. Times and Gaz., 1875, Vol. I, p. 657; and Q. C. SMITH—*Formulas for diarrhœa and dysentery in children*, Pacific Med. and Surg. Jour., Vol. VIII, 1874–5, p. 132: "℞ Fluid extract of ergot ʒj, fluid extract of golden seal ʒss. Mix. To small children, give from half to one teaspoonful, at intervals of one to four hours, as the case may require. For dysentery, with bloody discharges." The number of children who may have survived this medication is not reported. See also E. T. COMEGYS, Assistant Surgeon U. S. A.—*Fluid extract of ergot in diarrhœa*, The Med. Record, New York, Vol. XI, 1876, p. 565.

‡ SAVIGNAC—p. 390, *op. cit.*, p. 620, *supra.*

§ See, on the subject of ergotism, STILLÉ—Vol. II, p. 686, *op. cit.*, p. 711, *supra.*

‖ HARLES—*loc. cit.*, note †, p. 763, *supra.*

¶ TRIPLER—*loc. cit.*, *supra.* He states that it was suggested to him some three years before by Dr. FOSTER of Cincinnati, who mentioned that "he had seen surprising results in a case of chronic diarrhœa, from the use of very small doses of Fowler's solution."

** The use of Fowler's solution in the chronic fluxes is spoken of favorably in the reports of STORROW—p. 43, *supra;* TAYLOR—p. 87; and FOOTE—p. 90. BROWN—p. 81—states that he was disappointed with it. H. N. FISHER—*loc. cit.*, p. 697, *supra*—remarks that some of the patients to whom he gave it improved, while others did not. C. H. RAWSON—*loc. cit.*, p. 744, *supra*—affirms that it often "acts admirably" in "continued diarrhœa."

†† SYDNEY RINGER—*Handbook of Therapeutics*, 2d Ed., London, 1871, p. 197, and 4th Ed., Amer. reprint, New York, 1875, p. 253; the 1st Ed., published in 1869. I have not seen—recommends it in a form of diarrhœa connected with chronic dyspepsia which "appears to depend on excessive peristaltic action of the stomach and intestines, whereby the food, before it is digested, is driven from the stomach to the intestines, and thence expelled." He adds: "Arsenic will often be found of service in other chronic forms of diarrhœa, even when due to serious organic disease, as the bowel ulceration of phthisis, etc."

‡‡ I have previously expressed this view—p. 261, *op. cit.*, p. 606, *supra*, and *Circular No. 6*, p. 126, *op. cit.*, p. 571, *supra*—but was, I think now, to blame for referring to the use of arsenic in the fluxes without pointing out more clearly the dangers attending its use.

prison hospital. I have already presented conclusive evidence that the enthusiastic views which he entertained are not supported by the record; indeed, he collected his facts in so loose a manner that, as I have shown, some of the patients he supposed he had cured were already dead when he made his report. The views announced in his paper were not confirmed by subsequent experience in the Rock Island hospital, and the trials at Camp Dennison were also unsuccessful. Sound theoretical reasons for the internal administration of bromine or iodine in the fluxes have not been advanced, and the trial that has been made condemns them as useless if not actually injurious.*

Chlorate of potassa has recently been commended, both in diarrhœa and dysentery, by a few physicians,† but I know of no valid reasons for expecting benefit from its use.‡ Nor do I allude to *aconite* or *veratrum viride*, which have sometimes been employed to control the febrile symptoms in the early stages of acute dysentery, except for the purpose of advising the reader to avoid them.§

A variety of other substances have been recommended, of which some have become obsolete, while so little evidence has been advanced in behalf of others that it is unnecessary to discuss them.‖ Nor shall I attempt to enumerate all the ridiculous nostrums suggested by ancient or mediæval superstition, although it would be very easy to collect a great deal of curious information on this head did time and space permit.¶

---

* See the report of GILBERT in Section II, p. 52, *supra*. He dissolved six drops of bromine with fifteen grains of bromide of potassium in an ounce of water and gave drachm doses every two hours, or gave ten-drop doses of a solution of two grains of iodine dissolved in water by means of iodide of potassium. The case book and hospital register of the Rock Island hospital have enabled me to expose the errors into which he fell—see p. 53 *et seq.*, *supra:* see, also, his paper, *Bromine in the treatment of diarrhœa and dysentery*, The Chicago Med. Examiner, Vol. V, 1864, p. 657. At a meeting of the surgeons on duty at Camp Dennison—*Proceedings of the Dennison Medical Society, Jan.* 17, 1865, The Cincinnati Lancet and Observer, Vol. VIII, 1865, p. 279—Dr. CHAPMAN stated that he had tested the bromine treatment "to a considerable extent, and that in the main he had been disappointed with the results; yet in a number of instances, it had acted very happily. He had not fully determined the peculiarities of the cases that were benefited. He was still investigating the subject." At the meeting of the same society March 7, 1865—*op. cit.*, p. 341—however, CHAPMAN modified this statement, saying, "he had tried the bromine treatment, but only one case was benefited by it." So far as I know, the only observations that appear to support GILBERT'S view with regard to bromine are related in one of the clinical lectures of my distinguished friend N. S. DAVIS (of Chicago)—*Chronic diarrhœa—Camp diarrhœa*, &c., The Chicago Med. Examiner, Vol. V, 1864, p. 561—who states that, having learned the method during a professional visit to Rock Island, he commenced using it immediately upon his return, and remarks, "thus far its effects have fully answered my expectations." It would appear from a subsequent publication—*Chronic army diarrhœa*, same Jour., Vol. XII, 1871, p. 157—that he was still using the bromine treatment as late as February, 1871; but I regard these reports rather as indications that my friend was impressed by Dr. GILBERT'S enthusiastic statements than as expressions of any very great experience with the remedy. I note also a favorable report with regard to the use of iodine in chronic diarrhœa by E. L. SHURLY (of Michigan)—*Compound solution of iodine in chronic diarrhœa*, Buffalo Med. and Surg. Jour., Vol. X, 1871, p. 302.

§ See the account of the use of aconite by MARBOT in the febrile stage of acute dysentery on board the "Crocodile" off the coast of Zanzibar in October, 1844, in an article entitled *Quelques mots sur le traitement de la dyssenterie, et en particulier sur l'emploi de l'aconit napel dans cette maladie*, Bull. Gén. de Thér., T. XXXVII, 1849, p. 105. With regard to *veratrum viride*, see, for example, A. M. RAGLAND—*Veratrum viride in dysentery*, The Medical Archives, (St. Louis,) Vol. IV, 1870, p. 279.

‖ I may mention here *pareira brava*, which, during the last century, enjoyed a short-lived reputation in the treatment of dysentery: see PLANQUE—T. IV, p. 22, *op. cit.*, p. 690, *supra; Collect. Acad.*, Partie François, T. III, 1769, p. 526; and GEOFFROY—T. II, 1743, p. 33, *op. cit.*, p. 707, *supra*. The *betel nut*, (fruit of areca catechu:) see F. PERON—*Sur la dyssenterie des pays chauds, et sur l'usage du bétel*, Corvisart's Jour. de Méd., Chir., Pharm., &c., T. IX, 1805, pp. 57 and 183. Powdered *gum guaiac:* see J. W. STERLING—*A new remedy in acute dysentery*, The New York Jour. of Med., Vol. I, 1848, p. 370. *Chloride of barium:* see A. WALSH—*Muriate of barytes in diarrhœa*, Dublin Med. Press, Vol. XIX, 1848, p. 322. *Glycerine:* see J. DAUDÉ—*Note sur un nouveau mode de traitement de la dysenterie*, L'Union Médicale, T. XI, 1857, p. 569. *Propolis:* see H. O. HITCHCOCK—*Propolis as a remedy for diarrhœas, acute and chronic*, The Chicago Med. Jour., Vol. XXIV, 1867, pp. 417 and 485. *Guarana:* see HERVÉ—*Emploi du guarana dans les diarrhées rebelles*, Bull. Gén de Thér., T. LII, 1857, p. 418. The *spinal ice-bag:* see JOHN CHAPMAN—*Diarrhœa and Cholera*, 2d Ed., London, 1866, p. 29. The list might be extended to almost any length, but it would answer no useful purpose to do so.

¶ Some of these have already been alluded to in note ‡, p. 739, *supra*, and in note ‡, p. 811, *supra*. I will only make mention, in addition, of a few which are still praised in the posthumous works of ETTMÜLLER—T. I, Cap. 9, p. 127, *op. cit.*, p. 647, *supra:* "*Priapi:* Priapus cervi, tauri et ceti, quos inter ipsos priapus ceti est omnium optimus, post hunc est priapus cervi, vilissimus est priapus tauri." These may be smoked dry and powdered, and as much as an ounce given at a dose, alone or mixed with other medicines; or a decoction may be prepared from them. He gives in detail a number of formulæ, and cites authorities in proof of the excellent effects produced. Although burnt bones and horns are no doubt useful, yet above all the *human cranium*, properly pulverized, is a remarkable specific in dysentery, especially if it be taken from a man who has perished by a violent death. Moreover, the *lichen* that grows on the human cranium exposed to the weather, *usnea humani cranii*, (lichen plicatus,) has often been demonstrated to possess curative virtues; that is best which forms on the skull of a man who has been hanged or broken on the wheel. He praises, besides, the tooth of a hippopotamus; the blood of a hare hunted to death; the livers of snakes, vipers and frogs, especially in malignant dysenteries; stercus canis in goats' milk with sugar; horses' hoofs toasted, &c. Compare the Amsterdam edition of his Opera, Vol. II, 1697, p. 156 *et seq.*

MEDICATION BY THE RECTUM.—The history of enemata goes back at least to the time of the ancient Egyptians, who, as Herodotus testifies, had a custom of using emetics and clysters three days in every month for the purpose of preserving their health.* The Greek physicians made great use of clysters in the treatment of the fluxes, particularly in dysentery and the cœliac flux, preferring this method to medication by the mouth whenever they supposed the morbid process to be seated chiefly in the large intestine.† Sometimes they injected whey, milk, ptisan, broth of spelt and the like, intending thus to wash out acrid humors from the bowel and favor the efforts of nature to evacuate them; sometimes they aimed to sheath the intestinal mucous membrane, and protect it against acrid humors descending from above, by injecting oleaginous and gummy substances; or they endeavored

* HERODOTUS—*Euterpe*, Cap. 77: "Of the Egyptians, those who inhabit that part of Egypt which is sewn with corn, in that they cultivate the memory of past events more than any other men, are the best informed of all with whom I have had intercourse. Their manner of life is this. They purge themselves every month, three days successively, seeking to preserve health by emetics and clysters; for they suppose that all diseases to which men are subject proceed from the food they use."—Cary's transl., Amer. Ed., New York, 1855, p. 124.

† See note †, p. 362, *supra*. A word may be said here with regard to the instruments originally employed for the purpose of administering clysters. A bladder with a pipe tied in its orifice was the simple means first used. This was no doubt the method employed by the Egyptians, as it was long afterwards by the Greeks, Arabians and modern Europeans. The apparatus recommended in the Hippocratic treatise *De his quæ uterum non gerunt*, [Ed. Littré, VIII, 431,] for vaginal injections differed from this only in having a number of little orifices in the sides of the pipe. The apparatus described by AVICENNA—Lib. III, Fen 16, Tract. 4, Cap. 11, p. 843, *op. cit.*, p. 632, *supra*—which was devised to provide for the escape of flatus simultaneously with the introduction of the clyster, was more complicated, but the propulsive power was still exerted by means of a bladder. And the same is true of the two forms of apparatus figured by FAB. HILDANUS—Cap. X, p. 690, *op. cit.*, p. 644, *supra*. One of these is a beef bladder with a short wide tube tied in its orifice; this tube is provided with a stop-cock, and serves to fill the bladder for use, after which the pipe fits in with a slip-joint. This appears to have been the form then commonly in use. The other is claimed by HILDANUS as his own invention, and could be used for self-injection as well as to administer clysters to others. In it the bladder has tied into it at one extremity the same fittings as the first apparatus; at the other extremity a long thick tube is tied in, which is provided with a stop-cock at the end next the bladder, while near the other end the slender tube for insertion into the anus projects at right angles. The first metallic syringe for this purpose is figured in the work of MARCUS GATINARIA—*De curis ægritudinum particularium*, Lyons, 1525, fol. 44. From the figure, it appears to have been a straight cylinder, from one end of which the anal pipe projected, while a solid cylinder of metal inserted at the other end served as a piston. Attached to the anal pipe and parallel with it is a second smaller pipe intended for the escape of flatus. The figure in the edition of 1532 is shaded somewhat differently, but represents essentially the same thing; that in the edition of 1560 is a fac-simile of the one in the edition of 1525; and that in the Frankfort edition of 1604 is copied on a rather larger scale from the edition of 1532. See Fig. B. GATINARIA ascribes this clyster apparatus to AVICENNA. MALGAIGNE—*Œuvres d'Ambroise Paré*, T. I, Paris, 1840, Introduction, p. xcix—regards the Italian as the genuine inventor of the modern syringe: "Gatenaria décrit la seringue sous le nom d'instrument à clystères, et il juge même nécessaire d'en donner la figure; mais, comme la plupart des inventeurs de cette époque, il n'ose pas de sa propre autorité introduire une si grande innovation dans la pratique; il se réfugie derrière Avicenne, qui en a donné la description, dit-il, mais qui a été mal compris par plusieurs. Cette déclaration du modeste auteur nous oblige cependant de déclarer qu'il n'y a absolument rien de semblable dans Avicenne." On the other hand, E. COLSON—*De la méthode intestinale*, Paris Thesis, No. 113, 1867, p. 15—insists that GATINARIA did no more than copy AVICENNA, as he himself says he did. BROCHIN—Art. *Lavement*, Dict. Encyclopédique des Sci. Méd., 2me Série, T. II, Paris, 1869, p. 85—however, advocates the view of MALGAIGNE, remarking that it is sufficient to compare the two descriptions to be satisfied that there is only a very distant resemblance between the two intruments. I confess that, with nothing but the two descriptions before me, I should believe that GATINARIA had simply copied the Arabian physician, and that both had used a double-barrelled pipe, with the larger barrel attached to a simple bladder or bag, the fluid being injected through this larger barrel while the smaller was intended to serve for the escape of flatus. The figures in the work of GATINARIA, however, suggest more than his description. I append the two descriptions for the judgment of the learned reader. AVICENNA—*loc. cit.*, *supra*—writes: "Melior quidem cannæ clysteris figura, quam antiqui dixerunt, est ut sit circulatio cannæ ejus divisa per tertiam et duas tertias, et sit positum inter utranque velamen de corpore, de quo facta est canna, et sit consolidatum cum canna consolidatione vehementi, sit ergo velamen ejus duarum partium diversarum. Et sit uter decenter aptatus in parte, quæ duarum partium major est, et sit in parte minore apertus. Et quando uter decenter aptatus est super totam cannam, stringatur caput partis minoris cum consolidatione forti, ut non ingrediatur ipsam aer, et sit ei sub utre in loco, qui non ingreditur anum, meatus, per quem egrediatur ventositas. Quum enim administratur clystere, et exprimitur cum fortitudine ventositas, egreditur enema, et sistitur enema bene, ventositas. Enim est, per quam redit ad exitum et facit necessitatem surgendi ad sellam cum velocitate." GATINARIA—*loc. cit.*, *supra*: "Hæc est forma clisteris quam non intelligunt multi: et quam describit Avicenna scilicet quod pars superior scilicet canna ejus sit dupla ad partem inferiorem et mediet inter has partes medium unum sicut paries dividens partes illas sicut est in duabus fistulis conjunctis: et habeat pars minor unum foramen in parte quæ est prope conjunctionem bursæ clisteris: et aliud in opposito directe secundum longitudinem quod sit apud foramen partis grossioris: per quam partem majorem cui contignatur maxime bursa transeat aquositas enematis imposita per utrem: per inferiorem vero cannam sive minorem pulsa ab enemate ventositate per utris compressionem ipsa ventositas egrediatur: et hoc patet in figura et reddent dicta cum causa literam Avicennæ obscuram claram." The observation of HELIDÆUS of PADUA, that dysentery may be communicated to healthy individuals by means of the clyster-pipe, has already been referred to—p. 647, *supra*. On the other hand, BANKIER—p. 53, *op. cit.*, p. 637, *supra*—relates, on the authority of Dr. BARRY, that "in the years 1797, 1799, the dysentery prevailed in the Caithness legion of Fencibles to some extent. The Surgeon, anxious to determine the question as to its infectious nature, caused the same clyster pipe to be used, without cleansing, for these labouring under dysentery, and those who were free from the disease.—the latter notwithstanding were not infected." This filthy experiment is not very conclusive, in the absence of information as to the character of the epidemic, and I incline strongly to the prudent advice of HEUBNER—S. 542, *op. cit.*, p. 529, *supra*—that, if possible, each patient should have his own bedpan or night-stool, enema-syringe, &c. Certainly where the same syringe has to be used for different individuals it should be thoroughly cleansed and disinfected each time it is used.

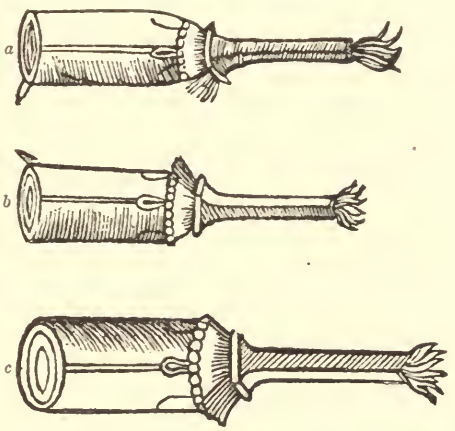

FIG. B.—Fac-similes of the cuts representing the enema apparatus of GATINARIA. *a*, In the edition of 1525; *b*, in the edition of 1532; *c*, in the edition of 1604.

to check the flux by injecting astringent decoctions of various kinds, and to allay pain by clysters containing opium, hyoscyamus and other narcotics; finally, in ulcerative dysentery and in the cœliac flux, they essayed to stimulate the intestinal ulcers to cicatrization by enemata containing various styptic and escharotic mineral substances, such as alum, the scales and oxide of copper, quicklime and the native sulphurets of arsenic.* These more potent substances appear to have been avoided by Celsus,† but the Arabians adhered in this respect to the Greek practice,‡ which survived the middle ages and still found defenders as late as the sixteenth century.§

About this time, however, a prudent opposition to the employment of enemata containing caustic or corrosive substances began to make itself felt. Rondeletius held that the practice of the ancients in this respect should not be imitated, for orpiment, quicklime and the like must act as caustics to the intervening surface of the intestines as well as to the ulcers. His views were shared by Felix Plater, Forestus, Hildanus, Septalius and Sennertus.‖ Hildanus pointed out that gangrene is produced by the external application of arsenic, and indignantly asked what else was to be expected if it be applied to so delicate a surface as that of the intestines. These physicians used in dysentery demulcent clysters of barley water, syrup of roses, yolks of eggs and other bland substances, to which, while the pain was acute, they added opium or other anodynes, and in the advanced stages relied on decoctions and infusions of the vegetable astringents, to which they sometimes added burnt hartshorn, Armenian bole and other drying remedies, or mastic, frankincense and other resinous drugs, believed to be possessed of healing virtues.

Zacutus Lusitanus¶ vainly attempted to combat the new views, declaring that it was better to inject even quicklime and arsenic than to let the patient die. His protest failed to check the general movement in the direction of reform; indeed, objections began to be heard even against the more innocent enemata which still continued in use. That wild

* The following are references to some of the most important passages in Greek medical writers referring to the use of clysters in the fluxes: In the Hippocratic treatise *De morbis mulierum*, Lib. I, § 109, [Ed. Littré, VIII, 233.] will be found a formula for a clyster to be used in dysentery, consisting of the dried rind of pomegranate boiled in wine with the addition of honey and oil; also, for tenesmus, an injection containing incense and rose oil with barley water and boiled sea water; and another composed of an infusion of hellebore with oil. The use of enemata of boiled milk in dysentery is commended in the treatise *De affectionibus, loc. cit.*, note *, p. 689, *supra*. Among the enemata commended by GALEN I may mention *whey*, either unmodified or that in which heated stones or iron has been quenched to give it astringency—*De simp. med. temp. ac fac.*, Lib. X, Cap. 2, [Ed. Kühn, XII, 266;] *hydromel* and *cream of ptisan*—*Comm. VI in Hippoc. Epidem.*, VI, § 5, [Ed. Kühn, XVII, B, 329;] *broth of tragus, goats' suet* and *rose cerate*—*Comm. II in Hippoc. Epidem.*, II, § 17, [same Vol., A, 352.] and *Meth. med.*, Lib. XII, Cap. 1, [Ed. Kühn, X, 813,] I suppose this tragus to be the spelt, described in *De aliment. fac.*, Lib. I, Cap. 13, [Ed. Kühn, VI, 519;] decoctions of various *astringent herbs* and *fruits*, such as the pomegranate, quince, &c.—*De remed. parab.*, Lib. I, Cap. 13, [Ed. Kühn, XIV, 380;] clysters of *brine* are useful for cleansing the dysenteric ulcers, if they become putrid—*Comm. I in Hippoc. de Humor.*, § 12, [Ed. Kühn, XVI, 146.] A considerable number of formulæ for clysters recommended in dysentery and the cœliac flux will be found in the treatise *De comp. med. secundum locos*, Lib. IX, Cap. 5, [Ed. Kühn, XIII, 295 *et seq.*] Some of these are lauded as anodynes, (sedans dolorem,) and contain *opium* and *hyoscyamus* variously combined with other remedies, chiefly aromatic and astringent, while others contain the styptics and escharotics referred to in the text, such as *alumen, squamæ æris, æs ustum, calx viva, sulfur vivum, cadmia, sandaracha* (red sulphuret of arsenic) and *auripigmentum*, (yellow sulphuret of arsenic,) to which *galls, gum tragacanth* or *gum acacia, opium, hyoscyamus*, &c., were frequently added. The following is a sample of these formulæ: "*Infusum aliud ut Idius.* ℞. Aeris usti 3xxiv, calcis vivæ, aluminis scissi, utriusque tantundem, chartæ ustæ 3xxx, auripigmenti drach. xij, sandarachæ drach. xij, excipe vino myrteo aut rosarum decocto, quæ cum vino austero ad dimidias coctæ sint et expressæ, atque ita lævigatas forma in pastillos, eosque infunde cum aqua."—*Ib.*, p. 297. Recipes for injections of the same character as those preserved by GALEN will be found in the works of ORIBASIUS—*Collect. Med.*, Lib. VIII, Cap. 25, T. II, p. 225, Ed. cited p. 683, *supra;* ÆTIUS—Tetrab. III, Serm. I, Cap. 45 and 49, pp. 605 and 612, Ed. cited p. 656, *supra;* and ALEXANDER of TRALLES—Lib. VIII, Cap. 8 and 9, pp. 451 and 461, Ed. cited p. 624, *supra*.

† CELSUS—Lib. IV, Cap. 15, Vol. I, p. 296, Ed. cited p. 656, *supra*—directs in chronic dysentery injections of cream of ptisan, milk, melted fat or deers' marrow, oil or butter with rose oil, raw whites of eggs with the same, decoction of linseed, and yolks of eggs with decoction of rose leaves. He adds that THEMISON recommended strong brine for the same purpose, and that a piece of minium triturated with salt, then mixed with water and injected, has a powerful influence on intestinal ulcers—see notes * and †, p. 763, *supra*.

‡ See RHAZES—*Ad Mansor. de re med.*, Lib. IX, Cap. 72, p. 259, Ed. cited p. 678, *supra*, and *Ad Mansor. antidotis*, Lib. I, Cap. 40, p. 475, same Vol.; also AVICENNA—Lib. III, Fen 16, Tract. 2, Cap. 7, T. I, p. 823, Ed. cited p. 632, *supra*, and Lib. V, Summa 2, Tract. 6, T. II, p. 330.

§ See, for example, HOLLERIUS—*De morb. intern.*, Lib. I, Cap. 40, fol. 120, Ed. cited p. 680, *supra;* and ZACUTUS LUSITANUS—*loc. cit.*, note ¶, *infra*.

‖ RONDELETIUS—*Meth. cur. morb.*, Lib. III, Cap. 21, p. 462, Ed. cited p. 680, *supra;* FORESTUS—Lib. XXII, Obs. 34, Scholium, p. 381, Ed. cited same page; HILDANUS—Cap. X, p. 689, *op. cit.*, p. 644, *supra;* FELIX PLATER—T. III, p. 811, *op. cit.*, p. 680, *supra;* SEPTALIUS—Lib. VII, § 102–3, p. 229, *op. cit.*, same page; SENNERTUS—T. III, p. 174, *op. cit.*, p. 645, *supra*. I note *urine* among the clysters commended by HILDANUS.

¶ ZACUTUS LUSITANUS—*De Med. Princip. Hist.*, Lib. II, Hist. 86, Paraphrasis, Vol. I, p. 332, *op. cit.*, p. 665, *supra*. I note, too, that SENNERTUS—p. 182, Vol. cited last note—while condemning the injection of these caustic substances in a general way, admitted that there might be desperate cases in which they were required.

enthusiast Van Helmont directed one of his wildest diatribes against this mode of treatment,* and although his followers were by no means numerous, yet even among other physicians clysters now began to be less indiscriminately employed. Ettmüller declared that by their abuse injurious effects were often produced; Hoffmann counselled caution even in the use of milk, gum, gelatine and the like, insisting that, instead of benefiting the patient, they often made the disease worse;† Van Swieten held that the quantity of fluid injected ought never to exceed three or four ounces;‡ while Degner went still further, and boldly affirmed that clysters were unsuited to the treatment of dysentery.§

It is true that this extreme view did not long maintain its ground; nevertheless, during the last century and the beginning of the present, physicians were for the most part cautious in the use of clysters for this disease. Zimmermann countenanced only the sparing use of infusions of chamomile or other bitter herbs and flowers, and expressed the opinion that clysters containing laxative, emollient and fatty substances are injurious.‖ Fournier and Vaidy admitted that emollient clysters are indicated in dysentery, yet thought that, unless great dexterity was employed in administering them, the irritation produced by the introduction of the clyster-pipe counterbalanced any advantages that might be expected.¶ Even during the last century, however, anodyne injections enjoyed a certain degree of popularity, and since the commencement of the present century there has been a general revival of medication by the rectum in dysentery.

Anodyne clysters.—Enemata containing some preparation of opium were, as has already been shown, very commonly employed in ancient medicine, and *suppositories* containing opium, with or without astringents, were frequently employed by both the Greek and Arabian physicians for the same purpose.** Gordonius declared, near the close of the thirteenth century, that such suppositories are a great remedy in dysentery,†† and his practice has

* VAN HELMONT—*Pleura furens*, § 28, p. 395, *op. cit.*, p. 488, *supra*. He argued that it must be fruitless to administer clysters in dysentery, which he held to affect only the small intestines, whereas the clysters reach only the large. It is therefore better to use some rational remedy, such as the dried and powdered penis of the stag or the bull; or, still more to be praised, the dried blood of a goat—not common blood, but blood obtained for this particular purpose from a he-goat, hanged by his horns to which his hind legs must be tied, by castrating him and allowing him to bleed to death from the wound—§ 32, p. 396. There was a noble gentleman who had been vainly treated by the court physician with more than 426 clysters, and yet after he had had 1,800 stools and more he cured him with medicaments given by the mouth alone. Do any of these Galenists imagine that they can cure intestinal ulcers by clysters? Let them remember, I beg of them, that, although the intestinal mucous membrane is insensible to the fæces, for which it is intended by nature, the clysters are foreign substances that can only excite pain and do harm. This error flows from the error of the schools in defining dysentery as ulceration of the intestines. Certainly I see that a bloody Moloch presides in the chairs of medicine. Repent, my professional brethren, for the world will one day shudder with dire horror at the sound of the trumpet when every one shall give an account of his stewardship.

† ETTMÜLLER—*loc. cit.*, note ¶, p. 824, *supra:* "Clysteres alias noti et frequentissimi sunt in dysenteria, sed sæpius pessimi: scilicet nimio abusu malum exasperant potius quam leniunt. Usus laudem habet, vituperium meretur abusus." In the explanations that follow, as in other parts of the same chapter, he avowedly follows VAN HELMONT, and yet he praises the rules laid down by SEPTALIUS, ("citato loco qui est elegans," referring to the passage from which I have cited, note ‖, last page,) who, though he objected to abstergent and caustic clysters, favored the moderate use of anodyne and emollient ones in suitable cases. HOFFMANN—T. III, p. 158, *op. cit.*, p. 681, *supra*, *Cautelæ, et monita practica*, *Sect. XI:* "Quamvis vero haud in totum improbari queant hæc remedia; monendos tamen esse duco medicos, ut in illis adhibendis cauti procedant, modumque servent. Nam fluida hæc glutinosa per anum admissa faciunt lentorem, ulcera magis fœdant, et cicatrici resistunt; efficiuntque sæpius, ut compresso alvi profluvio, ventris colluvies magis cumuletur, et fermentando graviores spasmos inducat ac tormina." Yet, after the noxious material was voided and the intestinal spasms quieted, he authorized the use of clysters of goat or deer suet, yolk of egg, turpentine or balsams.

‡ VAN SWIETEN—T. II, p. 391, *op. cit.*, p. 663, *supra*—writing of purgative enemata, which he regards as a useful aid to purgative medicines in getting rid of the irritating acrimony, says: "Ubi vero ad hunc usum clysmata adhibentur, requiritur, ut in adultis trium quatuorve unciarum quantitatem non excedant; sicque et proportionaliter in junioribus, ne nempe mole sua irritent intestina, sicque subito iterum per alvum exeant." He commends honey and water for this purpose in the quantity named, and, as will be mentioned further on, also approved of anodyne enemata.

§ DEGNER—Cap. V, § 31, p. 311, *op. cit.*, p. 625, *supra:* "Clysteribus dysenteriam curare, ejusque fluxum sistere velle, absonum mihi videtur; etenim illi non solummodo fontem mali non semper attingunt, sed etiam improvidus, aut nimis sæpe iteratus eorum usus majus incommodum inducit." In support of this view he gravely cites in a foot note the case related by VAN HELMONT—see note *, *supra*—in which 426 clysters were vainly given!

‖ ZIMMERMANN—Cap. X, S. 468, *op. cit.*, p. 648, *supra*. He holds besides that many clysters should not be administered, and that they should never exceed seven or eight ounces.

¶ FOURNIER et VAIDY—p. 385, *op. cit.*, p. 362, *supra*. They remark also: "Nous avons été obligés souvent d'y renoncer dans les hôpitaux militaires, où le soin d'administrer les lavemens est confié trop ordinairement à des infirmiers maladroits et ivrognes." A sad picture of the discipline of the military hospitals of that day! Let us hope our own are better managed.

** For formulæ for such suppositories (Greek, βάλανος or ὑποθετόν, Latin, glans) see, for example, ALEXANDER of TRALLES—Lib. VIII. Cap. 9, pp. 461–2, Ed. cited p. 624, *supra;* ÆTIUS—Tetrab. III, Serm. 1, Cap. 49, p. 616, Ed. cited p. 656, *supra;* and RHAZES—*Ad Mansor. de re med.*, Lib. IX, Cap. 72, p. 260, Ed. cited p. 678, *supra*.

†† GORDONIUS—fol. 162, *op. cit.*, p. 680, *supra:* "Si autem non possit dormire fiat suppositorium quod inducit somnum et constringit, et hoc est magnum remedium."

since found many imitators, although the majority of practitioners have preferred to inject the narcotic in a fluid form.* Enemata of this character were countenanced in most of the works on dysentery published in the sixteenth and seventeenth centuries, and continued to be employed after the use of almost all other clysters had fallen into discredit.†

Sydenham commonly administered clysters of milk and theriaca, regarding them as possessed of wonderful efficacy in checking the motions.‡ Van Swieten held this combination in equal esteem, although he preferred to use more theriaca and less milk.§ Pringle used emollient clysters, to which he added from twenty to fifty drops of laudanum, and thought this probably the best mode of giving opiates, though he admitted that he was often compelled to desist from using them on account of the local tenderness. Donald Monro declared that opiate clysters often gave more relief than anodynes administered in any other way.‖ Since then such injections have been commended by Blane, Hunter, Ballingall, Bampfield, Cheyne, Abercrombie, Annesley, Twining, Bankier, Hauff, Baly, Austin Flint, Bamberger, Morehead, G. B. Wood, Aitken, Savignac, Barrallier, Heubner and many other physicians.¶ Starch water or other mucilaginous fluids combined with laudanum have been the usual prescription, but other preparations of opium, as well as the extracts of hyoscyamus and other anodynes, have been employed. Several of the writers named favor also the use of opium suppositories as equal or even in some cases superior in their operation to the enemata. The notion has been generally entertained that the local symptoms, and especially the painful tenesmus, can be more efficiently controlled by these local applications than by the internal administration of the same drugs.

Nevertheless certain disadvantages, which have been conceded even by their advocates, attend the use of these enemata. Not infrequently the condition of the anus is such that even the most careful introduction of the clyster-pipe provokes serious irritation, and although the quantity of fluid injected be restricted as much as possible, its presence in the rectum often provokes a reflex action by which it is promptly expelled, so that the effect of the operation is to increase rather than to diminish the local irritation. Moreover, even when it is retained longer, the enema is so frequently expelled before the anodyne dissolved in it can be wholly absorbed that the physician must always feel a degree of uncertainty, as to just how much of the drug selected he is introducing into the circulation, which cannot fail to embarrass him in his management of the case.

These considerations have led many physicians, among them such skilful practitioners as Vogt and Niemeyer, to regard the use of these, and indeed of all other clysters, with

---

* Note how cautiously SENNERTUS—T. III, p. 176, *op. cit.*, p. 645, *supra*—speaks of the use of the suppositories commended by RHAZES.

† See, for example, the remarks on the use of narcotic clysters by ALTOMARUS—Cap. 74, fol. 184, *op. cit.*, p. 680, *supra;* and NICOLAUS PISO—Lib. III, Cap. 15, p. 277, *op. cit.*, p. 665, *supra*—both of whom professed the opinion of AVICENNA—see p. 736, *supra*—that narcotics can be given more safely by the rectum than by the mouth. See also HILDANUS—*loc. cit.*, note ‖, p. 826, *supra*, and SENNERTUS—*loc. cit.*, last note.

‡ SYDENHAM—*Med. Obs.*, Sect. IV, Chap. 3, Vol. I, p. 172, *op. cit.*, p. 407, *supra:* "Besides which, I give a clyster of half a pint of cow's milk, and half an ounce of Venice treacle, [*i. e.*, theriaca, see p. 730, *supra.*] This is thrown up every day, and is of wonderful efficacy in checking the motions."

§ VAN SWIETEN—§ 722, T. II, p. 394, *op. cit.*, p. 663, *supra*—taught that opium, or the compositions of the shops which contain it, if dissolved in milk and used as a clyster, check almost all alvine fluxes, (quasvis fere alvi dejectiones sistunt.) He particularly commends an ounce of theriaca in three or four ounces of milk.

‖ PRINGLE—p. 271 *et seq.*, *op. cit.*, p. 640, *supra:* "Although the advantage of clysters was manifest, yet we could not avail ourselves of them in the hospital so much as we wished; partly from the neglect of the nurses, and partly from the reluctance of the men to use them: even in private practice, we are frequently obliged to desist from them, on account of the tenderness of the parts." DONALD MONRO—p. 78, *op. cit.*, p. 625, *supra.*

B. WOOD—Vol. I, p. 724, *op. cit.*, p. 671, *supra;* AITKEN—Vol. II, p. 659, *op. cit.*, p. 647, *supra;* SAVIGNAC—p. 425, *op. cit.*, p. 620, *supra;* BARRALLIER—p. 782, *op. cit.*, p. 603, *supra;* and HEUBNER—S. 546, *op. cit.*, p. 529, *supra.* The last mentioned author, however, appears to give the preference to anodyne suppositories.

distrust, or to reject them altogether.* Tripler testified that in his experience anodyne enemata were apt to become of themselves sources of irritation and to aggravate the sufferings of the patients,† and Stillé entertained serious doubts whether enemata are ever useful in the acute stage of dysentery.‡ These objections, combined with the obstacles to this mode of medication usually encountered in the military service, served to limit the employment of anodyne enemata during our civil war. They are mentioned with favor by a few of the reporters;§ but the testimony presented is not sufficient to throw much light on the question of their real utility. For myself, while I do not doubt in the least that they are very often of apparent, and sometimes of real benefit, I think it probable that all the good they are capable of doing can be obtained with greater certainty by the hypodermic injection of morphia, and anticipate that with the extension of the latter mode of medication they will disappear from practice.

The introduction into the rectum of *carbonic acid gas* and of *vapor of chloroform* have been suggested with a view to the production of a local anæsthetic effect, but the evidence that beneficial effects can really be produced in this way is far from conclusive.‖ Quite recently, also, injections of the *hydrate of chloral* have been brought into use, but it would be premature as yet to express an opinion as to their value.¶

Astringent and drying clysters.—Infusions and decoctions of the various *vegetable astringents* continue to be occasionally employed as enemata in the later stages of acute dysentery and in the chronic fluxes. They were regarded with favor by Annesley, Bamberger, Savignac, Barrallier, Heubner and others,** and are usually administered in combination with some preparation of opium, but have not, during the present century, enjoyed the popularity of some of the substances of the group next to be mentioned. Among the *mineral astringents* that have been used as clysters, alum, the astringent salts of iron, the acetate and subacetate of lead, the sulphates of zinc and copper and the nitrate of silver may be particularly mentioned; each has had its advocates,†† but the salt last named has enjoyed by far the greatest popularity.

---

* VOGT—S. 188 *et seq.*, *op. cit.*, p. 645, *supra*. NIEMEYER—Bd. II, S. 756, *op. cit.*, p. 645, *supra*.

† TRIPLER—p. 33 *et seq.*, *op. cit.*, p. 691, *supra:* "In the more purely dysenteric cases, when the rectum is the chief seat of local difficulty, anodyne injections have long been favorite remedies. I cannot say that I have seen any decided benefit from them. They do seem to allay tenesmus for a while, and thus procure some little rest to the patient; but from their frequent repetition, they become themselves sources of irritation, aggravate the sufferings of the patients, and are, of necessity, abandoned."

‡ STILLÉ—p. 366, *op. cit.*, p. 650, *supra*—speaking of acute dysentery in patients who are "not of a vigorous constitution," says: "Enemata are useful in this form of dysentery, if in any acute form, of which there is serious doubt."

§ See, in Section II, the reports of STORROW—p. 43, *supra;* SCHÜSSLER—p. 44; PENROSE—p. 45; COUES—p. 64; JONES—p. 85; and GAGE—p. 93. I myself—p. 230, *op. cit.*, p. 606, *supra*—in 1863, regarded the employment of laudanum enemata in acute dysentery with favor; but I had not yet, at that time, become practically acquainted with the hypodermic method.

‖ Seltzer-water injections have been occasionally employed on account of the *carbonic acid gas* they contain. They have quite recently been praised by CONSTANTIN PAUL—*loc. cit.*, note ^, p. 773, *supra*—as a means of relieving tenesmus. MOREHEAD—vide *infra*—after suggesting the introduction of chloroform vapor through a caoutchouc tube, remarks: "If it be a therapeutic fact as stated by Dr. Simpson, that carbonic acid is anæsthetic and curative of foul ulcers, then applied by the same simple means it may be worthy of trial in chronic dysentery." I am not aware that this hint has been acted upon. The employment of *vapor of chloroform* for the relief of tenesmus was suggested by ETHRENREICH—*Chloroform-Dunst-Klystiere gegen Tenesmus bei der Ruhr*, Med. Zeit., Jahrg. XXII, 1853, S. 138—who introduced 30 drops of chloroform into a common syringe, allowed it to vaporize and injected the vapor, with great relief to the patient; he suggested that as much as a drachm might be used in this way. MOREHEAD—p. 394, *op. cit.*, p. 657, *supra*—remarks: "The vapour of chloroform introduced into the rectum, is probably deserving of a more extensive trial than it has yet had in the circumstances for which opiate enemata are usually employed. It might be conveniently applied by means of the simple caoutchouc cylinder and tube, used by Dr. Simpson, for conveying the vapour to the os uteri."

¶ Enemata of *hydrate of chloral* have been employed with apparent benefit by NEWELL, WHITAKER, TYSON and others—see p. 760, *supra*.

** ANNESLEY—Vol. II, p. 298, *op. cit.*, p. 621, *supra*—mentions particularly *tincture of catechu* as an addition to enemata composed of the infusion of cinchona, or of calumba, &c. BAMBERGER—S. 412, *op. cit.*, p. 578, *supra*—specifies particularly tannin, with or without opium; the other vegetable astringents he regards as less efficacious. SAVIGNAC—p. 428, *op. cit.*, p. 620, *supra*—commends, besides tannin, catechu, rhatany, oak-bark and other vegetable astringents. Oak-bark is the one he employs most frequently and with the greatest advantages. BARRALLIER—p. 783, *op. cit.*, p. 603, *supra*—does not mention tannin, but praises the other substances named by SAVIGNAC; and HEUBNER—S. 546, *op. cit.*, p. 529, *supra*—specifies rhatany and tannin.

†† A solution of *alum* and white vitriol was one of the enemata recommended by ROBERT JACKSON—p. 458, *op. cit.*, p. 770, *supra*—in chronic ulcerative dysentery. PARKES—p. 154, *op. cit.*, p. 682, *supra*—speaking of adynamic dysentery, wrote: "Injections of alum are very useful in that variety where the intestine is so disorganized as to tear like wet paper after death." D. DONOVAN—*Obs. on the diseases to which the famine of* 1847 *gave origin*, &c., Dublin Medical Press, Vol. XIX, 1848, p. 278—preferred injections containing alum and laudanum to those containing acetate of lead or nitrate of silver. HAMON—*De la dysenterie et de son traitement par le sulfate d'alumine et de potasse, en lavements*, L'Union Méd., T. XI, 1857, p. 347—elevated

The use of injections of the *nitrate of silver* in dysentery was suggested in 1817 by Robert Jackson, who, however, did not actually employ them. A weak solution was used, without decided results, by Cheyne in the Dublin dysentery of 1818, and Hudson testifies that he saw enemata containing this salt successfully administered to dysenterics by Osborne in 1831.* But it was undoubtedly the prominence given to such enemata by Boudin (1836) in connection with typhoid fever that led to their subsequent extensive trial in both acute dysentery and the chronic fluxes. Among those who have warmly advocated them I may mention Trousseau, Masselot and Follet, Garlike, Weatherby, Palmer, Bamberger, Fouquet, Duclos, Gros, Savignac, Caradec and Gestin.† During our civil war these injections were employed by several of the military surgeons, and an account of fifteen cases of camp diarrhœa thus treated under the direction of Assistant Surgeon A. Hartsuff, U. S. A., at the Judiciary Square hospital, Washington, D. C., during the summer of 1863, has been presented in a previous portion of this chapter.‡

When these clysters are to be administered the crystallized nitrate of silver is usually selected, dissolved in distilled water and injected with a glass syringe. The quantity of fluid used is generally small; in most cases two to six ounces. The strength of the solution most frequently employed is from half a grain to two grains to the ounce; but some physicians prefer stronger solutions, and as much as ten or fifteen grains to the ounce, or even more, have been injected with alleged advantage. Savignac has given the preference to a solution of nitrate of silver and chloride of sodium in albuminized water; his method

---

alum clysters to the principal position in the treatment of dysentery. In two epidemics (1854-5) in the department of the Sarthe, he relied exclusively on injections containing 4 to 8 grammes of alum; of 75 patients, two, old men, only died. See also VALÉRIUS—*Lavement aluné*, Bull. Gén. de Thér., T. LVIII, 1860, p. 168. PIEDVACHE—*Mémoire sur la dyssenterie épidémique et sur son traitement*, Gaz. Méd., T. XIV, 1859, p. 272—used it to some extent, and SAVIGNAC—p. 434, *op. cit.*, p. 620, *supra*—approved it, though he pointed out that, if the solution is too strong, it is prone to irritate, and advised, therefore, that it should not exceed 4 grammes to the quart of liquid. Injections of *perchloride of iron* have been commended by BAUDON—*loc. cit.*, note *, p. 773, *supra*, and PAUL—*loc. cit.*, same note; of *Monsel's salt* by L. MCGUIRE—*Chronic dysentery successfully treated with the subsulphate of iron*, Pacific Med. and Surg. Jour., Vol. III, 1869-70, p. 511. A solution of *acetate of lead* has been recommended for the same purpose by BALLINGALL—p. 78, *op. cit.*, p. 682, *supra*; CHEYNE—p. 51, *op. cit.*, p. 686, *supra*; and PARKES—p. 146, *op. cit.*—who writes: "Injections of the acetate of lead in large doses, such as one drachm every four hours, (!) are sometimes very useful. Injections of the *subacetate of lead* are praised by D. GUÉRAUD—*Du sous-acétate de plomb en injections intestinales dans la diarrhée et la dysenterie*, Paris Thesis, No. 58, 1855—who relates that BARTHEZ employed them with success in the dysentery prevailing among the troops of the garrison of St. Denis during the year 1844: they were also used by PIEDVACHE—*loc. cit.*, *supra*. SAVIGNAC—p. 433, *op. cit.*, p. 620, *supra*—held that injections of the subacetate are preferable to those of the acetate, but he advises care in their use lest the accidents of lead poisoning should supervene, and adds: "C'est une arme à tenir en réserve pour ne s'en servir qu'en cas de nécessité, lorsque l'on n'a pu retirer aucun profit des autres topiques modificateurs." I may add that injections containing *carbonate of lead* have been recommended by DEVERGIE—*Emploi de l'acétate de plomb décomposé par le carbonate de soude, pour arrêter la diarrhée des phthisiques*, Bull. Gén. de Thér., T. XI, 1836, p. 146—who advises every morning and evening an injection containing two grains of acetate of lead and one of carbonate of soda with four drops of Sydenham's laudanum dissolved in a decoction of linseed. Injections containing *sulphate of zinc* have been recommended by BALLINGALL—*loc. cit.*, *supra*—and by JACKSON—*loc cit.*, *supra*—who also commends *sulphate of copper* for the same purpose. BAMBERGER—*loc. cit.*, last note—mentions with approval alum, acetate of lead, sulphate of zinc, sulphate of copper, sulphate of iron and nitrate of silver, giving the preference to the latter. G. B. WOOD—*loc. cit.*, note ¶, p. 828, *supra*—approves acetate of lead, sulphate of zinc and nitrate of silver; HEUBNER—*loc. cit.*, last note—sulphate of zinc, acetate of lead, alum and nitrate of silver, yet admits that too much should not be expected of them. SAVIGNAC—p. 435, *op. cit.*—makes light of the sulphates of zinc and copper, regarding nitrate of silver as greatly superior.

* ROBERT JACKSON—*loc. cit.*, last note—after speaking of the efficacy of injections of "white vitriol and alum, blue vitriol, corrosive sublimate, &c.," writes: "A dilute solution of the nitrate of silver might be employed for the same purpose with a reasonable prospect of advantage, but I have not the satisfaction to say that I have seen it so employed." This passage is repeated in the second edition of his work—Vol. II, p. 64. CHEYNE—*loc cit.*, last note. HUDSON—*op. cit.*, note †, p. 779, *supra*.

† BOUDIN—*op. cit.*, note ‡, p. 778, *supra*. TROUSSEAU—*op. cit.*, note §, p. 778, *supra*; MASSELOT et FOLLET—1843, T. II, p. 174, *op. cit.*, p. 439, *supra*; W. GARLIKE—*On nitrate of silver in certain cases of dysentery*, &c., The Med. Times, Vol. XVIII, 1848, p. 57; J. S. WEATHERBY—*A notice of dysentery as it prevailed in Gordon and Cass counties*, Southern Med. and Surg. Jour., Vol. VII, 1851, p. 727; A. B. PALMER—*Report on dysentery*, The North-Western Med. and Surg. Jour., Vol. IX, 1852-3, p. 297; BAMBERGER—*loc. cit.*, note **, last page; FOUQUET—p. 214, *op. cit.*, p. 725, *supra*; DUCLOS (of Tours)—*Rech. sur l'emploi du nitrate d'argent dans la dyssenterie aiguë*, Bull. Gén. de Thér., T. LXI, 1861, p. 97; L. GROS—*Nouvelles obs. à l'appui de l'emploi du nitrate d'argent dans le traitement de la dyssenterie*, same Vol., p. 433; SAVIGNAC—p. 436, *op. cit.*, p. 620, *supra*; T. CARADEC—*Du traitement de la dysenterie par le nitrate d'argent*, L'Union Méd., T. XXI, 1864, pp. 233 and 259; and H. GESTIN—*Note sur une épidémie de dysenterie qui a régné à Brest depuis le mois d'Octobre, 1866, jusqu'en Mars, 1867*, Archives de Méd. Navale, T. VII, 1867, p. 321.

‡ See, in Section II, the reports of PENROSE—p. 45, *supra*; ELLINWOOD—p. 52; HARRISON—p. 82; WHITE—p. 85; GRANGER—p. 86; and COOPER—p. 93: besides HARTSUFF'S cases referred to in the text, viz: cases 4 to 18, inclusive—p. 48 *et seq.*, *supra*. One of these, case 8, was an intercurrent diarrhœa of brief duration in a wounded officer who died a few weeks subsequently. Of the fourteen remaining cases, five, viz: cases 6, 7, 10, 11 and 18, were shortly after transferred to other hospitals, where it is reported that they were still suffering from diarrhœa. The success of the method was not therefore very conspicuous. SAVIGNAC—*loc. cit.*, last note—regards a one-eighth to one-quarter of one per cent. solution as sufficiently strong. Some have ventured to use a one-half per cent. solution, (1 gramme to 200 grammes of water,) but this is not usually required. On the other hand, WARING—p. 103, *op. cit.*, p. 696, *supra*—gives a formula for an enema, used by MCGREGOR in chronic dysentery, containing 20 grains of the nitrate in two fluid ounces of mucilage combined with opium. HARTSUFF—*loc. cit.*—used 10 to 15 grains to the ounce of water.

of preparation is subjoined.* Barrallier, who admits that the product is complex and of uncertain composition, claims, nevertheless, that in practice it gives satisfactory results.† This modification of the silver method has not, however, attained general popularity.

Much less favorable results than those claimed for silver injections by most of the writers cited have, however, been obtained by other physicians who have used them. Baly, although he admitted that they were useful, preferred black wash and laudanum; Austin Flint reported six cases in which silver enemata were employed, with apparent benefit in but three; Vogt declared that in his experience they often produced pain and irritation; that weak solutions were seldom beneficial except in the mildest cases, and that stronger ones proved uncertain in their effects; Niemeyer counselled against employing such injections at all; and Heubner states that he resorted to them in the Franco-German war without any very definite results.‡

I incline to the opinion that the lavish praise bestowed by some writers upon this mode of medication is hardly warranted by the clinical details that have been reported; and although it is not surprising that the introduction of such a styptic into the rectum should sometimes, temporarily at least, check the flux, it is difficult to believe that the small quantity of solution usually injected is likely to reach the ulcerated surfaces that may exist in any part of the colon. This objection was long since recognized by Hare, who proposed to escape it by injecting fifteen grains of nitrate of silver, dissolved in two and a half or three pints of water, through a flexible tube introduced beyond the sigmoid flexure; all parts of the colon would thus be thoroughly reached.§ If the contact of the silver solution is so beneficial to the diseased mucous membrane as has been claimed, this method should certainly prove efficacious, yet few physicians have ventured to adopt it. Some success has, however, been obtained in chronic fluxes kept up by ulcers near the anus from the application, through a speculum, of a concentrated solution, or solid stick, of nitrate of silver directly to the ulcerated surface. Walsh cured a case in this way in 1848, and the method has since been employed with good results by Kennedy, Taylor, Maury and Dills, while T. Gaillard Thomas has successfully used pure nitric acid in the same manner.‖

---

* J. Delioux de Savignac—*Considérations chimiques, physiologiques et thérapeutiques sur les sels d'argent*, Gaz. Méd., T. VI, 1851, p. 553, and *loc. cit.*, note †, last page. His method is briefly as follows: The whites of one or two eggs are dissolved in 200 grammes of distilled water and filtered through a cloth; 50 centigrammes of nitrate of silver are then dissolved in a little distilled water in another vessel, and a solution of 50 centigrammes of chloride of sodium in a little distilled water is prepared in a third. The two saline solutions are then poured simultaneously into the solution of albumen, and the whole is stirred thoroughly with a glass rod. Thus prepared the solution is quite transparent and free from precipitate. It should always be used immediately after it is made, but the silver in this form is reduced so slowly by contact with metals that it is not necessary to employ a glass syringe. Savignac claims that this mixture is less irritating than a simple solution of the nitrate in distilled water and more efficacious. He thinks that the silver in this form is readily absorbed, which, if true, would in my opinion constitute a serious objection to its use; and in his enthusiasm goes so far as to suggest that it exercises a special dynamic influence on the disease, (whatever that may mean:) "Ils agissent plutôt dynamiquement que topiquement. L'argent aurait-il une influence spéciale sur les conditions essentielles de la dysentérie?"

† See Barrallier—p. 783, *op. cit.*, p. 603, *supra*.

‡ Baly—p. 537, *op. cit.*, p. 535, *supra;* Austin Flint—p. 212, *op. cit.*, note §, p. 710, *supra;* Vogt—S. 193, *op. cit.*, p. 645, *supra;* Niemeyer—Bd. II, S. 756, *op. cit.*, p. 645, *supra;* Heubner—S. 547, *op. cit.*, p. 529, *supra*.

§ E. Hare—*On the treatment of tropical dysentery by means of enemata of tepid water*, The Edinb. Med. and Surg. Jour., Vol. LXXII, 1849, p. 40. The method referred to in the text was employed in the treatment of chronic cases, and was preceded by the large injections of warm water which will be described further on. Among the physicians who have used injections of nitrate of silver in this way I may mention particularly my friend H. C. Wood—*On the rational treatment of dysentery*, Philadelphia Med. Times, Vol. VIII, 1877–8, p. 25—who remarks: "My experience in angina led me at once to fasten upon nitrate of silver in these experimental trials," and who ventured upon stronger solutions than were injected by Hare, whose method he follows, but to whom he does not allude. As to the quantity of the nitrate that may be used, he remarks: "Drachm doses of the nitrate have in no case produced any constitutional symptoms, and doses of less than forty grains have not accomplished much good. Twenty-five grains to the ounce is a very common strength for use in angina, and when a drachm of the nitrate is dissolved in three pints of water for an injection, the strength of the solution is only a little over a grain to the ounce." He reports one case of acute and six of chronic dysentery successfully treated with these injections.

‖ That Albert Walsh treated a case in this way in May, 1848, is stated by H. Kennedy—*On one of the forms of diarrhœa*, &c., The Dublin Med. Press, Vol. XXVI, 1851, p. 387—who reports a similar case successfully treated in the same manner by himself. Other cases are reported by Robert Taylor—*Report of a case of chronic diarrhœa, with muco-sanguineous discharges, depending upon ulceration of the rectum*, Buffalo Med. and Surg. Jour., Vol. IV, 1864–5, p. 8; Richard B. Maury—*Successful treatment of chronic dysentery by topical medication*, Atlanta Med. and Surg. Jour., Vol. X, 1872–3, p. 516; and M. Dills—*The topical treatment of chronic dysentery*, New York Med. Jour., Vol. XXIII, 1876, p. 396. See also T. Gaillard Thomas—*Remarks on chronic dysentery, with the history of a case of five years standing, cured within five weeks by topical treatment*, same Vol., p. 1.

Of the *drying remedies* the *subnitrate of bismuth* is the only one which has attracted much attention as a clyster in modern times. Such enemata, recommended by Monneret,* have been used to a limited extent; but it is so easy to bring this insoluble powder into contact with all parts of the alimentary canal by administering it by the mouth in adequate doses that it can rarely be necessary to employ it by the rectum.

Iodine clysters.—Injections of iodine were first employed in dysentery by Eimer, who reported the success of his trial in 1851, and have been adopted to a limited extent in Germany, where they have been praised especially by Mauthner.† In France they have enjoyed a greater reputation. Here they were independently experimented with by Savignac, whose first account of his trials was presented to the Academy of Medicine in the summer of 1852, and who has zealously claimed as against Eimer the doubtful honor of having been the first to use the method; Chapuis, Aran and Bossu claim to have employed it with success.‡ The method of Eimer was to inject twice a day or oftener five to ten grains of iodine dissolved with as much iodide of potassium in two or three ounces of water; Savignac used tincture of iodine with iodide of potassium in the same way. Eimer employed these injections in acute dysentery, and thought they exerted a local antiphlogistic action; Savignac limited their use in acute dysentery to obstinate cases, employed them especially in chronic fluxes, and supposed them to act constitutionally as well as locally.

Vogt, who gave this method a fair trial during 1853 and 1855, has exposed without pity the objections to it. He found that weak solutions were well borne, but of little benefit, while stronger ones often gave rise to severe pain without checking the dysentery, or actually served to make it worse. The action of the remedy, both as to the production of pain and its effect upon the flux, was very uncertain; some patients, indeed, recovered, but in others the treatment gave rise to so much local trouble that it had to be abandoned; in no case could he detect any beneficial effect which could be attributed to the absorption of the iodine.§ Little has been heard of this method of medication of late,‖ and the hope may be expressed that it will become obsolete.

Ipecacuanha clysters.—Injections of infusion or decoction of ipecacuanha were already employed in the treatment of dysentery by Helvetius in the latter part of the seventeenth

* MONNERET—T. LXXI, 1866, p. 484, *op. cit.*, note *, p. 789, *supra*. I may add that HARE—p. 40, *op. cit.*, note §, last page—sometimes used with his long tube a mixture of catechu and chalk, and with alleged benefit.

† EIMER—*Zur Therapie der Ruhr*, Zeitschr. für rat. Med., Bd. X, 1851, S. 238. From a remark on S. 241 it appears that he used the method in the autumns of 1849 and 1850. MAUTHNER—*Klinische Mittheilungen*, Jour. für Kinderkrankheiten, Bd. XXII, 1854, S. 246—found these injections useful in the dysentery of children.

‡ According to his own account, SAVIGNAC made his first trials of this method in the latter part of the year 1851, that is, after EIMER'S paper was published. He presented his memoir on the subject, upon which he relies for priority, to the Academy of Medicine July 20, 1852—Bull. de L'Acad. Nat. de Méd., T. XVII, 1851-2, p. 879. This memoir was not published till the next year; it was entitled *Essai sur l'emploi des injections iodées dans le traitement de la dyssenterie chronique*, Gaz. Méd., T. VIII, 1853, pp. 197, 211 and 734. It was also published separately by J. B. BAILLIÈRE, Paris, 1853. For his first reclamations against EIMER, see his paper entitled *De l'emploi des injections iodées dans le traitement de la dyssenterie*, Bull. Gén. de Thér., T. XLIV, 1853, p. 28; they are repeated in his treatise on dysentery—p. 441, *op. cit.*, p. 620, *supra*. To establish his unjust claim SAVIGNAC is driven to pretend that EIMER'S first publication is no earlier than the abstract of it inserted in the Bull. Gén. de Thér., November 30, 1852. The original paper, published in 1851, he entirely ignores. It has been quite *la mode* for French *savants* to deal in this manner of late with German rivals, but a more scandalous illustration of this particular phase of national vanity I do not remember to have encountered. The method finally adopted by SAVIGNAC was to dissolve 10 to 20 grammes of tincture of iodine in 200 to 250 grammes of water by the aid of half a gramme to a gramme of iodide of potassium—p. 442, *op. cit.* He regards it as applicable to acute dysentery when the disease resists other means, but especially to dysenteric diarrhœa and chronic dysentery—p. 445. After the administration of such injections iodine can be detected in the urine and saliva, and the patient recognizes its taste. It probably, therefore, acts constitutionally as well as locally—p. 448. The observations of CHAPUIS, who used the method with alleged success in the dysentery of Martinique, are contained in a letter which SAVIGNAC has published in his essay cited above—Gaz. Méd., T. VIII, p. 734. F. A. ARAN—*Note sur l'épidémie actuelle de choléra-morbus et sur son traitement*, L'Union Méd., T. VII, 1853, p. 610—employed it with success in the diarrhœas of epidemic cholera. The observations of BOSSU are reported by A. L. H. MONTOZON—*De l'heureux emploi de la teinture d'iode dans le traitement de la dysenterie chronique*, Paris Thesis, No. 11, 1856.

§ VOGT—S. 191, *op. cit.*, p. 645, *supra*.

‖ I may note here the suggestion of H. M. LYMAN—*loc. cit.*, p. 709, *supra*—that the compound tincture of iodine dissolved in glycerine with a little extract of belladonna may successfully be "carried to the seat of the disease," by means of a long flexible injection-pipe, when the flux is kept up by ulcers of the sigmoid flexure. He claims to have derived great benefit from this method, but in the only case particularized as having been "cured" in this way, the disease returned a few months after.

century,* and were revived by Abercrombie in the early part of this.† Since the modern revival of the internal administration of ipecacuanha in dysentery they have come into more general use. Massey used ipecacuanha in enemata with laudanum in 1859, but was not satisfied that he saw any marked benefit from this mode of treatment;‡ Whittingham, Warburton Begbie and Dyce Duckworth report a greater degree of success.§ Injections containing powdered ipecacuanha beaten up with mucilage have been resorted to with alleged advantage by Jessop, Barter, Ferrell and Birch.‖ In France injections of a decoction of ipecacuanha have been lauded by De Mussy in dysentery and chronic diarrhœa, by Chouppe in cholera infantum and various forms of diarrhœa.¶ Any discussion as to whether the decoction or the powder suspended in mucilage is the better form for ipecacuanha clysters, may well be postponed until more conclusive evidence is brought forward than is afforded by the papers just cited that either produces effects, in this way, which cannot be obtained equally well by the internal use of the drug. Meanwhile the fashion which is bringing ipecacuanha clysters into vogue has at least the merit of affording a less objectionable substitute for the too frequent use of clysters of iodine and nitrate of silver.

Antiseptic clysters.—The putrid character of the discharges from the bowels in many forms of flux, and the belief that the absorption of putrid matters from the alvine contents frequently aggravates the constitutional condition of the patient, has not unnaturally suggested the attempt to modify or arrest the putrefactive changes, going on in the contents of the colon, by means of antiseptic clysters. Pringle relates that Hunter, one of the surgeons in the expedition to Portugal, frequently used a strong decoction of Peruvian bark with this view.** The same speculation appears to have led to the use of clysters of chamomile flowers and other bitters which were employed by Zimmermann and others.†† The infusion of Peruvian bark was used for the same purpose by Ballingall and Annesley; the latter sometimes substituting infusion of calumba.‡‡ These and other tonic infusions or decoctions have been occasionally employed by subsequent physicians, sometimes with a view to their antiseptic action, but perhaps more frequently with the expectation of producing a tonic effect, or even with no other intent than to secure the slight astringent action belonging to most articles of this class.§§ Clysters containing *charcoal*, to which attention was directed by Robert Jackson, have since been employed for their antiseptic effect by Bankier, Savig-

* See note ‡, p. 692, *supra*. † ABERCROMBIE—p. 280, *op. cit.*, p. 553, *supra*. ‡ MASSEY—*op. cit.*, note †, p. 696, *supra*.

§ RICHARD WHITTINGHAM—note †, p. 697, *supra*. J. WARBURTON BEGBIE, in the course of the discussion of MCKIDD'S paper—cited note ‖, p. 696, *supra*—mentioned that he had frequently used injections of ipecacuanha in chronic diarrhœa, and often with good effect. DYCE DUCKWORTH—Vol. VII, p. 117, *op. cit.*, note †, p. 699, *supra*—mentions also that such injections had been commonly employed in India.

‖ C. M. JESSOP—*Ipecacuanha in dysentery*, The Indian Med. Gaz., Vol. VI, 1871, p. 139—used 10 grains of powdered ipecacuanha with half a drachm of laudanum and two ounces of decoction of arrowroot or of mucilage: an injection was given three times daily. J. F. BARTER—*The treatment of dysentery*, same Vol., p. 181. H. V. FERRELL—*Treatment of dysentery by ipecac enemata*, The Clinic, Vol. II, 1872, p. 74—used three times a day an enema containing a drachm of powdered ipecacuanha in six ounces of mucilage of acacia: eleven cases were thus treated successfully. In eight of them no other medication was employed. E. A. BIRCH—*On some practical points in the treatment of the acute infantile bowel complaints of India*, The Indian Annals of Med. Sci., Vol. XVIII, 1876, p. 347.

¶ NOËL GUÉNEAU DE MUSSY—*Some observations on the local action of ipecacuanha*, The Practitioner, Vol. XIII, 1874, p. 185, also *Clinique Médicale*, T. II, Paris, 1875, p. 109. H. CHOUPPE—*De l'emploi de l'ipéca dans le choléra infantile, et quelques autres formes de diarrhée*, Le Progrès Médical, 1873, Nos. 20, 23 and 27, (the Vol. for this year is not in our library,) and 1874, pp. 39 and 75; also, by the same—*Note sur l'emploi d'ipécacuanha administré en lavements dans la diarrhée cholériforme des jeunes enfants, et dans la diarrhée des tuberculeux*, Bull. Gén. de Thér., T. LXXXVI, 1874, p. 481.

** PRINGLE—p. 275, *op. cit.*, p. 640, *supra:* "At this time, supposing that the rectum, from the irritation occasioned by the incessant motions, tended to a mortification, I endeavoured to quiet the spasms by repeated anodyne clysters, but without any antiseptic ingredient. Something however of that kind has been tried by others. For Mr. Hunter, one of the surgeons on the expedition to Portugal, told me, that he had frequently used antiseptic clysters with good effect, when the patient was worn down with continual motions and a tenesmus. His first trial was with four ounces of a strong decoction of the bark, in which he dissolved some grains of opium; and afterwards, he found that a decoction either of the tormentil-root, or of oak-bark, with opium, answered the same purpose."

†† ZIMMERMANN—*loc. cit.*, note ‖, p. 827, *supra*.

‡‡ BALLINGALL—p. 78, *op. cit.*, p. 682, *supra;* ANNESLEY—p. 298, Vol. II, *op. cit.*, p. 621, *supra*.

§§ See, for example, the remarks of SAVIGNAC—p. 429 *et seq.*, *op. cit.*, p. 620, *supra*—on clysters of decoction of Peruvian bark and infusion of chamomile. These clysters are also commended by BARRALLIER—p. 783, *op. cit.*, p. 603, *supra*—who, however, classes them among astringent clysters. In like manner HEUBNER—*loc. cit.*, p. 829, *supra*—classes simaruba and calumba among the astringents that may be used as clysters.

nac, Farre and others.* For the same purpose *chloride of lime* was used by Bankier and Schneider; *Labarraque's solution* by Cornuel, Savignac and Morse; the *hyposulphite of soda* by Paul; and *creasote* by Willmott, Gairdner and Schneider.†

Additional prominence has been given to remedies of this class by the speculation that the presence and multiplication of low vegetable forms in the alimentary canal cause the fluxes. They are supposed not only to produce the septic metamorphoses occurring in the intestinal contents, but to give rise to the inflammatory processes in the intestinal mucous membrane, and, by invading the lymphatics and bloodvessels, to enter the torrent of the circulation and produce the constitutional disturbances that accompany the flux. If this view were correct, what more efficient means could be found to destroy the living cause of the disease than antiseptic injections? We may fail in our attempts to introduce efficient doses of antiseptic substances into the blood, or to give enough by the mouth to produce any very great effect in the lower bowel, but how easy to fill the colon, if necessary, with substances that will destroy low vegetable forms of life. Accordingly, as Christian Langius resorted to enemata acidulated with oil of vitriol, by which he hoped to destroy the vermiculi he imagined to produce fluxes,‡ the modern believers in *contagium animatum* have employed injections of diverse substances for the purpose of killing the bacteria. *Carbolic acid* has been used for this purpose by Flügel and others; *salicylic acid* by Brünniche, Trier and Berthold.§ The new speculation, like the old one, is unproven, but it is not necessary to accept either in order to recognize the benefits likely to ensue in appropriate cases from the injection of antiseptic substances, provided those are selected which are not injurious in their action upon the inflamed mucous membrane. From this point of view salicylic acid would appear preferable to carbolic.

Clysters of water.—The great importance attached by the Greek physicians and their followers to the injection of emollient fluids for the purpose of washing out the acrid contents of the colon in dysentery, and the apparent benefit that often followed the use of this class of clysters, has not unnaturally suggested the idea that the same good effects might be produced by means of water alone. Some, not content with the mere cleansing action of that fluid, have endeavored to increase its effect by modifying its temperature. Accordingly the superiority of *cold water* thus used has been insisted on by Baker, Bailey, Blades,

---

* ROBERT JACKSON—Vol. II, p. 47, *op. cit.*, p. 830, *supra*—relates that he first learned to use powdered charcoal in dysentery in 1814. He gave it by the mouth as well as by clyster, and writes: "In all cases of diseased secretion from the interior membranes of the intestinal canal, whether in children or in adults, the effect of the powder now mentioned, was sovereign,—not less specific in this than Peruvian bark is in the cure of regular intermittents." BANKIER—p. 169, *op. cit.*, p. 637, *supra*—writes: "In those cases in which the stools have a very offensive smell, and in particular if the disease has been of long standing, we may often change this for the time being by an enema of starch and carbonus ligni or a solution of the chloruret of lime." He rubbed up the charcoal with starch, then mixed with water and a little opium. SAVIGNAC—p. 429, *op. cit.*, p. 620, *supra*—observes: "Je signalerai l'utilité toute spéciale des lavements au charbon dans les cas de selles abondantes et très-fétides." He prescribes 20 or 30 grammes of powdered charcoal in 500 grammes of decoction of linseed, or, in the gangrenous form of dysentery, in as much decoction of Peruvian bark. See also FARRE—*Good effects of charcoal enemata on the evacuations of dysentery*, The Lancet, 1862, Vol. I, p. 515.

† For *chloride of lime clysters*, see BANKIER—*loc. cit.*, last note—and SCHNEIDER—S. 32, *op. cit.*, p. 813, *supra*. For *clysters of Labarraque's solution of hypochlorite of soda*, see CORNUEL—p. 147, *op. cit.*, p. 615, *supra;* SAVIGNAC—p. 430, *op. cit.;* and E. M. MORSE—*A new treatment for chronic dysentery*, California Med. Gaz., Vol. I, 1868-9, p. 55. CORNUEL mixed half an ounce to an ounce of Labarraque's solution in four or five ounces of fluid, and thought it especially useful in cases with purulent stools. This opinion was shared by SAVIGNAC, who regarded these clysters as producing a beneficial modification of the intestinal mucous membrane, besides acting as an antiseptic. He held, however, that the dose should not exceed 8 grammes to each injection, on account of the local irritation it is apt to produce if too strong. MORSE boldly employs one part of Labarraque's solution to twenty of water, and thinks two or three pints usually enough to give at a time. On the use of *hyposulphite of soda* for the same purpose, see PAUL—*loc. cit.*, note *, p. 773, *supra*. For commendations of *creasote clysters*, see J. B. WILLMOTT—*On the use of creosote injections in camp dysentery*, London Med. Gaz., N. S., Vol. I, 1845, p. 162; W. T. GAIRDNER—*Clinical notes*, The Edinburgh Med. Jour., Vol. V, 1859-60, p. 994; and SCHNEIDER—*loc. cit.*, *supra*.

‡ CHRISTIAN LANGIUS—*loc. cit.*, note †, p. 811, *supra*. He recommended that the quantity of oil of vitriol added to the clyster should be just sufficient to communicate the slightest acidity to the taste. I cannot avoid thinking that if modern physicians would act on this practical hint, taste their clyster fluids, and administer nothing in this way that they would think unfit to be swallowed, it would be better for their patients.

§ FLÜGEL—*Bemerk. über die Ruhr und ihre Behandlung*, Ditterich's Blätter für Heilwiss., Jahrg. IV, 1870, S. 171. Injections of *salicylic acid* (1 part to 500) were used with alleged benefit in the Communal-hospital at Copenhagen by BRÜNNICHE in 1875 and F. TRIER in 1876; I cite from the Jahresbericht of Virchow and Hirsch, Jahrg. XI, für 1876, Bd. II, Abth. I, S. 210. A. BERTHOLD (of Dresden)—*Therapeutische Erfolge der Salicylsäure bei verschiedenen Krankheiten*, Archiv der Heilk., Jahrg. XVII, 1876, S. 261—used successfully in dysentery 2 grammes of salicylic acid to 200 of water.

Campbell, Grant, Wenzel and others.* Both Baker and Wenzel aimed at producing a local antiphlogistic effect by this method of applying cold during the inflammatory stage of acute dysentery; and both advised that ice should be added, if necessary, to reduce the temperature sufficiently. On the other hand, *hot water* has been recommended as preferable under the same circumstances by Gordon, Reid and others. Reid recommends that it should be used every two hours at a temperature of 100° to 110° Fahr., points out that vaginal injections of this temperature produce blanching and contraction of the mucous membrane with consequent diminution of the calibre of the canal, and infers that a similar effect will be produced in the colon and rectum.†

More important was the endeavor of Hare to increase the efficiency of water clysters by throwing them in through a flexible tube passed beyond the sigmoid flexure, which permits a much larger quantity of fluid to be introduced without inconvenience, and the large intestine to be really washed out. This plan was suggested by the previous attempts of O'Beirne, who had used a flexible tube in the same way for the introduction of purgative clysters in dysentery.‡ O'Beirne's chief aim was to remove accumulations of hardened fæces, but Hare pushed the idea to its logical results. His view was that the long tube changes a huge internal abscess into an external lesion, enabling us not only to wash it out and cleanse it from its putrid contents, but to employ local applications at pleasure. He especially insisted upon the idea that the grave lesions of the colon, encountered in serious dysenteries, are chiefly due to the prolonged sojourn in that part of the bowel of the acrid materials, which are too rapidly moved along the small intestine to produce similar effects in that portion of the intestinal canal.§ This view is quite in accordance with the old Greek pathological notions; is it or is it not in accordance with the actual facts? The method of Hare was used with success by James Irving and some other physicians in Bengal,‖ yet

* W. BAKER, in a letter to JOSEPH KENT—The Philadelphia Jour. of the Med. and Physical Sciences, Vol. I, N. S., 1825, p. 411—writes: "I use very COLD WATER, (rendered so even by ice,) thrown up the bowels in form of an enema, every half hour. * * * If the gut be topically affected with heat and inflammation, what, let me ask, can be more likely to allay that inflammation, than bathing the inflamed coats of the intestine with cold water?" F. K. BAILEY—*Dysentery*, The North-Western Med. and Surg. Jour., Vol. IX, 1853, p. 386. F. BLADES—*Cold water in dysentery*, Vol. X, 1853. p. 152. CAMPBELL—Vol. XIV, 1858, p. 83, *op. cit.*, p. 402, *supra*. ALEXANDER GRANT—*Remarks on hill diarrhœa and dysentery*, Indian Annals of Med. Sci., Vol. 1, 1853-4, p. 328; and B. WENZEL—*Zur Behandlung der Ruhr*, Berliner klin. Wochensch., Jahrg. X, 1873, S. 575. HEUBNER—p. 543, *op. cit.*, p. 529, *supra*—accuses these cold-water enemata of increasing the tormina. Cold water enemata have also been employed in chronic cases by M. J. B. MESSEMER—*Cold water enemata as a therapeutic agent in chronic diarrhœa*, The Amer. Jour. of the Med. Sciences. Vol. LXXVI, 1878, p. 133—who claims that they possess "astringent properties."

† GORDON—*loc. cit.*, note ‡, p. 769, *supra*. J. J. REID—*Treatment of acute dysentery by injections of hot water*, The New York Med. Jour., Vol. XXIV, 1876, p. 603.

‡ JAMES O'BEIRNE—*New views of the process of defecation*, &c., Amer. Ed., Washington, 1834, p. 85—held that in dysentery "the chief curative indication should be to pass up the gum elastic tube and introduce it into the sigmoid flexure, in order to give exit to the accumulated and pent up contents of the cæcum and colon." In the appendix to this work he writes: "Dysentery having just reappeared in this city, I have had opportunities of trying my novel mode of treating the disease." He then relates two cases in which the flexible tube was used, and injections of from one to four pints of warm water with one or two ounces of castor oil and as much olive oil thrown in. The result in each case was the evacuation of considerable quantities of hardened fæces with mucus and flatus, and the relief of the symptoms.

§ E. HARE—p. 54, *op. cit.*, p. 831, *supra:* "The substance, then, of the whole argument is this. The long tube changes a huge internal abscess into an external, and enables us to wash out and cleanse from it its putrid contents. It also enables us to foment and soothe, by *local* applications, the sloughing and ulceration these contents have caused on its surface." He remarks: "And can I be wrong in concluding, that dysentery in its primary nature, as seen in the small intestines, and parts of the colon protected from the secretions, is a mild and harmless disease, and that, therefore, if we remove quickly these acrid secretions, we shall disarm dysentery of its terrors?" With these views he begs his readers not to "cease repeating the injection till you are satisfied that the colon is evacuated and cleansed"—*loc. cit.* See also a later article by the same physician—p. 485 *et seq.*, *op. cit.*, note *, p. 401, *supra:* "The moment a patient was admitted, his bowels were thoroughly washed out by a powerful syringe, with a flexible tube passed above the sigmoid. Warm water without limit in quantity was then slowly injected by a powerful pump, till the patient complained of the distension, and the abdomen was visibly enlarged." Then, after describing an apparatus suitable for these injections, he remarks that it is equally desirable to wash out the dysenteric colon when its contents are liquid as when they are solid, for the liquid contents also, "whether bilious, or secretions from the inflamed mucous membrane itself, are always in all forms of dysentery intensely acrid. The whole object then of the treatment is, to wash out these carefully, to constantly renew the ablutions and fomentations with warm water enemata, and to calm with opiates or bleeding, the constitutional excitement. * * * By passing an elastic tube beyond the sigmoid, I have found in more than three hundred cases of the severest form of dysentery, not the slightest difficulty in washing out the colon, from cæcum to anus. * * * Wash out the colon, and we place it in the same condition as the small intestine, and save it from disease. * * * In treating 346 cases in Calcutta, I had but 4¾ per cent. deaths."

‖ JAMES IRVING—*Cases of dysentery treated by enemata of warm water*, The Edinburgh Med. and Surg. Jour., Vol. LXXI, 1849, p. 101—remarks, after speaking of the observations of O'BEIRNE and HARE: "This plan is now extensively adopted in Bengal, and has been used to some extent in the artillery hospital at Subathoo." He himself contributes the details of five cases treated with success by this method; but to these enemata he often added, "with advantage, a few drops of laudanum and a few grains of acetate of lead."

did not succeed in obtaining recognition as a common mode of treating dysentery. The inconvenience of faithfully employing it was no doubt an obstacle, but various theoretical objections were urged against it which prevented any very extensive trial.

Morehead earnestly denied that dysentery is mainly kept up by the acrid nature of the secretions that enter the large intestine, thought that in this disease the coats of the intestine were often so friable that the distension produced by large injections would be dangerous, and argued that the plan of Hare claimed a therapeutic importance for the application of warm water to the intestinal mucous membrane unwarranted by anything known of its effect upon external inflammations. Vogt declared that he was unable to conceive how Hare had succeeded in introducing such large quantities of water; in his experience it often happened that small quantities, not exceeding two ounces of the blandest fluids, were immediately rejected, in spite of every possible precaution to secure their retention.* But neither of these excellent physicians professes to have tried the method of Hare even in a single case, and therefore their plausible arguments contribute nothing to the decision of the practical questions: Are such injections well borne? Do they do good?

Dulles reports that Monti has recently employed large enemata of water with advantage in various disorders of the large intestine, using a long flexible tube, and relying upon gravity, instead of the force-pump used by Hare, to secure the introduction of the fluid. He himself relates a case of infantile enteritis successfully treated in this way.† Certainly the method would seem well worthy more extended trial than it has as yet received. But in future attempts in this direction it would appear desirable not only that the fluid injected should be as nearly as possible of the temperature of the body, but that chloride of sodium or some other neutral salt should be added to it to make its specific gravity approximate that of the blood in order that the disturbing influence of rapid endosmotic processes may be avoided. The practice of the Greeks, who commonly used clysters of whey or barley water for the purpose of washing out the intestine, had at least this advantage over simple water, but with our present views the addition of some substance not itself prone to enter into fermentation at the temperature of the body would appear preferable.‡

---

* MOREHEAD—p. 309, *op. cit.*, p. 657, *supra*. VOGT—S. 189, *op. cit.*, p. 645, *supra*.

† C. W. DULLES—*Irrigation of the large intestine*, Philadelphia Med. Times, Vol. VIII, 1877, p. 125. The method is ascribed to ALOIS MONTI of Vienna. Two practical points are insisted upon in the paper: First, the superiority of gravity injections over those thrown in by the intermittent action of a syringe; and second, that the rectum should be distended with fluid before attempting to pass the tube through the sigmoid flexure, thus rendering its passage safe and easy.

‡ In this place I may refer to an interesting paper by ROBERT BATTEY (of Rome, Georgia)—*Permeability of the entire alimentary canal by enema, with some of its surgical applications*, Virginia Med. Monthly, Vol. V, 1878, p. 551. In this paper, which is a synopsis of an essay presented to the American Medical Association in June, 1878, the author states that in March, 1873, while giving a large clyster of soap and water to a sick woman, she recognized the taste of soap in her mouth. In January, 1874, he established the feasibility of injecting fluids into the anus of a cadaver until they escaped by the mouth. He then cites several cases in which castor oil injected into the rectum has been vomited, and claims to have discovered "the new fact of the entire permeability of the canal by enema." He remarks: "This discovery, made by the writer as before stated, upon the 3d of March, 1873, was certainly new to him, and he believes was equally new to the profession when he brought it before the Atlanta Academy of Medicine in May, 1874, and published it to the world in the Atlanta Medical and Surgical Journal in June of that year. He, therefore, feels warranted in claiming it as his original discovery, until some other member of the profession shall manifest a disposition to contest the claim and possess himself of any credit which may be attached to it"—p. 556. See, also, by the same author, *Intestinal obstructions; a safe and ready method*, Atlanta Med. and Surg. Jour., Vol. XII, 1874–5, p. 129; the cases reported by A. B. COPELAND and T. S. MITCHELL—same Jour., Vol. XIII, 1875–6, p. 269; and the case reported by H. M. HEARN—*Castor oil vomited up forty minutes after being injected into the rectum*, Nashville Jour. of Med. and Surg., Vol. XIV, 1874, p. 220. Dr. BATTEY makes his claim to priority so modestly that I regret to deprive him of any credit that may belong to it; but unfortunately the facts do not support it. A. GUAYNERIUS, who flourished in the fifteenth century, in his *Tractatus de fluxibus*, Cap. 2—I cite the Lyons Ed. of 1534, fol. 136—relates the story of a man who vomited a suppository previously introduced into his rectum. J. MATTHIAS DE GRADIBUS, in his *Practica*, *De Aegritudinibus stomaci*, Cap. 5, *de vomitu*, fol. 213, Venice Ed., 1502, relates the case of a girl twelve years old, suffering from ileus, who not only vomited fæcal matters but afterwards clysters, which were rejected by the mouth shortly after they were introduced into the anus. This state of things lasted for three days, during which suppositories introduced into the rectum were vomited in the same manner; and when it was attempted to keep a suppository in place by a string, the string broke and it was speedily vomited. SENNERTUS—T. III, p. 95, *op. cit.*, p. 645, *supra*—who cites these cases, together with one observed by J. OPTHEUS, in which a piece of tallow candle, used as a suppository, was vomited shortly after its introduction, uses them to support his speculation that ileus is not due to actual obstruction but to a reversal of the peristaltic movement of the intestine. I. DE DIEMERBROECK—*Anatomes* Lib. I, Cap. 8, Opera, Utrecht, 1685, p. 36—relates a case in which a suppository, and one in which a clyster was vomited. I had made notes of these observations for another purpose before I read Dr. BATTEY's paper. I have made no attempt to search for others, except to look into the work of MORGAGNI—*op. cit.*, p. 538, *supra*—in whose *Thirty fourth Epistle*, § 29, references will be found to a number of such cases. That prudent observer has well presented the matter,

Other clysters.—Among the other substances that have been employed in this way may be mentioned *corrosive sublimate*, used by Robert Jackson and Kopp; *black wash*, by Cheyne, Annesley and Baly; *infusion of tobacco*, by Abercrombie and Bampfield; *warm wine*, by Cazin; *turpentine emulsion*, already tried by Cheyne, which subsequently enjoyed considerable popularity; *chlorate of potassa*, recommended by Löbel and Mead; and *glycerine*, by Daudé.* It would be easy, but it is unnecessary, to extend this list, nor is it worth while to dwell upon the various *purgative clysters* that have been prescribed, such as *soap and water* by Jackson, or *castor oil* by O'Beirne and others;† however convenient this method of administering purgatives has been found in other diseases, it may well be doubted whether it is not better in the case of the fluxes to give them by the mouth only, and to rely for evacuating the lower bowel, if enemata are used at all, upon large injections of warm water prepared as indicated in the preceding paragraph.

EXTERNAL MEDICATION.—Fomentations, cataplasms and plasters of various kinds, applied externally to the abdomen, played a prominent part in the treatment of fluxes by the Greek physicians and their followers. Directions for a variety of such applications have been preserved by Ætius in his account of the treatment of dysentery: Wool sprinkled with oil of rue and powdered cummin; cataplasms containing astringent herbs, which were supposed to exert in this way also a restraining influence upon the flux; anodyne cataplasms containing opium, hyoscyamus and aromatics; as well as plasters composed of pitch, resin, myrrh, pepper and the like are among the remedies he enumerates.‡ In obstinate fluxes, such as the cœliac affection, Archigenes did not hesitate to apply the actual cautery to the surface of the abdomen, or, if this was refused by the patient, to produce eschars by the

---

when he suggests, "you would, I suppose, say that the throwing up of glysters by the mouth, was not a very rare thing, but would not say that it is frequent." Experiments on the dead body to show that fluid can be injected through the whole alimentary canal have been made by ALFRED HALL—*On the efficacy of large purgatite clysters in certain forms of obstinate constipation of the bowels,—together with a series of experiments upon living and dead bodies, undertaken to determine the extent to which fluids may, per anum, be injected into the intestines*, read before the Med.-Chir. Society of Glasgow, Oct. 28, 1845, The Monthly Jour. of Med. Sci., Vol. V, 1846, p. 1. In one of these experiments "eight pints of water were thrown up without any difficulty, the fluid passing through the *whole course of the intestines*, and partially filling the stomach." Other experiments on the subject with like results have been made by G. SIMON—*Ueber die Einführung langer, elastischer Rohre und über forcirte Wasserinjectionen in den Darmcanal*, Archiv für klin. Chir., Bd. XV, 1873, S. 122 *et seq.*; and F. KÖSTER—*Ueber grössere Darminjectionen und deren Heilwirkungen, insbesondere bei Ileus*, Inaug.-Diss., Erlangen, 1874. Moreover, besides the attempts to apply the knowledge obtained by these experiments to practical uses by the authors cited, I may refer to the paper of C. ISNARD (of Marseilles)—*Des injections forcées dans l'occlusion intestinale*, Gaz. Méd., T. XXI, 1866, p. 777—who maintains that with proper precautions it is a comparatively easy thing to cause the injection fluid to pass beyond the ileo-cæcal valve in the healthy subject. I may add that Dr. ARNOTT is cited by JAMES SCOTT—*Commentaries on the use and necessity of lavements*, &c., London, 1829—as having written: "From an erroneous opinion, that what has been called the valve of the cæcum acts as a perfect valve, allowing passage *downwards* only, few practitioners have ventured to order much liquid to be injected, for fear of over-stretching or bursting the lower part of the intestine; and the possibility of relieving disease *above* the supposed valve has scarcely been contemplated. It is now ascertained, however, that fluid may be safely injected, even until it reach the stomach"—Note, pp. 82-3. I shall not attempt in this place to discuss the practical uses of injections thrown beyond the ileo-cæcal valve, which I should certainly not employ in diarrhœa or dysentery.

* Enemata of *corrosive sublimate* are generally attributed to KOPP, (1821,) see note †, p. 724, *supra*, but they had been used by ROBERT JACKSON—p. 458, *op. cit.*, p. 770, *supra*—prior to 1817. He remarks: "Injection of soap and water—warm and in large quantity for the purpose of washing of foulnesses, followed by injections in small quantity—not exceeding two or three ounces of solution of white vitriol and alum, blue vitriol, corrosive sublimate, &c., afford relief in many cases, and even contribute materially in some to effect a permanent cure." *Black wash* (formed by the addition of calomel to lime water) was used by CHEYNE—*loc. cit.*, note ††, p. 829, *supra*—but without decisive results; on the other hand, ANNESLEY—Vol. II, p. 299, *op. cit.*, p. 621, *supra*—thought it useful when the bowels were ulcerated; and BALY—p. 537, *op. cit.*, p. 535, *supra*—regarded it as preferable to the nitrate of silver. An *infusion of tobacco* is praised by ABERCROMBIE—p. 280, *op. cit.*, p. 553, *supra*—and BAMPFIELD—p. 127, *op. cit.*, p. 682, *supra*; the latter did not hesitate to inject an infusion made with a drachm of tobacco leaves. I may add that I. DE DIEMERBROECK—*Obs. et cur. med.*, *Obs.* 18, in Opera Omnia, Utrecht, 1685—has recorded the story of a young man who swallowed without the counsel of a physician, while laboring under dysentery, an infusion made with half an ounce of tobacco in beer. Violent vomiting and purging followed, with danger to life, but the patient survived and the dysentery was cured. DIEMERBROECK adds that he has heard of two other rustics who cured themselves of dysentery in the same way, but he regards the method as dangerous. This observation appears to have suggested the subsequent use of tobacco clysters. CAZIN—see an article entitled *De l'emploi des lavements de vin chaud dans la diarrhée chronique*, Bull. Gén. de Thér., T. XL, 1851, p. 136—recommended clysters of *warm red wine*, containing one or two yolks of eggs, as both nourishing and astringent. *Emulsion of oil of turpentine* was used as a clyster in dysentery by CHEYNE—*loc. cit.*—but without marked benefit. For *chlorate of potash* clysters, see LÖBEL—*Dysenterie*, Bericht der k. k. Krankenanstalt Rudolph-Stiftung in Wien vom Jahre 1867, S. 131—and THEODORE MEAD—*Of the use of chlorate of potash and glycerine injections for the ulcerations in chronic dysentery*, New York Med. Jour., Vol. XVIII, 1873, p. 265. For *glycerine* clysters, see DAUDÉ—*loc. cit.*, note ‖, p. 824, *supra*—who commends in epidemic dysentery the use twice daily of 30 grammes of glycerine with 150 grammes of decoction of flaxseed or bran.

† JACKSON—see note *, *supra*; O'BEIRNE—see p. 835, *supra*.

‡ ÆTIUS—Tetrab. III, Serm. 1, Cap. 45, p. 603, and Cap. 50, pp. 617-8, Ed. cited p. 656, *supra*. In the latter chapter the plasters are described under the head of *dropaces*.

operation of caustic drugs.* Many of the external applications employed by the Greeks were adopted by the Arabian physicians, who also added others of similar character. They employed baths, frictions, inunctions, cataplasms and plasters of diverse kinds for this purpose,† and regarded counter-irritation by dry cups on the abdomen as a potent means of checking fluxes, as has already been mentioned.‡

It would occupy too much space to trace in detail the subsequent history of remedies of this class. The importance with which they were regarded by the physicians of the seventeenth century will, however, be apparent to any one who will take the trouble to look over the long list of liniments and ointments, cataplasms and plasters, spice-bags and fomentations, hip-baths and anal fumigations enumerated in the work of Sennertus.§ Nor would it be difficult to find many, among modern practitioners, who regard their favorite external applications with as much confidence as Sir Gilbert Blane reposed in measures of this class.‖ I suppose at the present time the majority of physicians will agree that the application of astringent fomentations and poultices to the external surface of the abdomen is quite futile; and also, notwithstanding the favor with which belladonna plasters were regarded in certain quarters twenty years ago,¶ that the good effects of anodynes, when these are indicated, can be more satisfactorily obtained by their administration internally, or by means of the hypodermic syringe; but the local application of heat by fomentations and poultices, and various modes of producing local counter-irritation are still regarded with so much favor as to require brief mention.

Warm applications, whether in the form of fomentations or poultices, are undoubtedly agreeable to many patients when the gripings are frequent and painful. They certainly often produce a sense of relief, and having once been tried are asked for again and again. It can hardly be imagined, however, that they exercise any very decided influence on the progress of even trifling fluxes. Savignac justly points out that when the evacuations are frequent these applications are apt to be displaced and chilled, if the patient is permitted to rise to use the close-stool,** and that they may thus do more harm than good. This inconvenience can, however, be avoided by the judicious use of a towel or broad bandage to retain the dressing in position; and, moreover, in serious cases, as already pointed out, the patient ought not to be permitted to rise.†† Hélye has insisted that the application of dry warmth to the abdomen by means of numerous thicknesses of woollen cloth is the most important part of the treatment of dysentery.‡‡ Certainly this is a greatly exaggerated view. Indeed, on trial the application of moist heat will generally be found more comforting to the patient; yet the method of Hélye, which is usually acceptable, is sometimes preferred, and is far less troublesome than the systematic use of moist heat. The

* In ÆTIUS—Tetrab. III, Serm. I, Cap. 37, p. 591: "Quod si tamen prædicta remedia circa affectionis solutionem nihil efficiant, ustio adsumatur. Perurere autem superiorem ventrem oportet, intervallis duorum digitorum mensu aut amplioribus etiam factis, ulcerationesque servare ad multum tempus ad fluxionum in ventre transitum ac derivationem. Licet autem et per pharmacum crustas infligere, si quis ignis admotionem formidet." According to ZIMMERMANN—S. 469, *op. cit.*, p. 648, *supra*—RESTAURAND in the seventeenth century published several observations of cases of obstinate diarrhœa and dysentery which he had cured with red-hot irons. And I note that BENEDICT SYLVATICUS—*Consil. et Respons. Med.*, Geneva, 1662, Cent. II, Cons. 92, p. 190—advises the application of an issue to the left arm as a derivative in dysentery.

† See, for example, AVICENNA—Lib. III, Fen 16, Tract. 1, p. 816, Ed. cited p. 632, *supra*. ‡ See p. 684, *supra*.

§ SENNERTUS—T. III, p. 180 *et seq.*, *op. cit.*, p. 645, *supra*. ‖ BLANE—p. 461, *op. cit.*, p. 637, *supra*.

¶ See note ‡, p. 733, *supra*. ** SAVIGNAC—p. 334, *op. cit.*, p. 620, *supra*. †† See p. 656, *supra*.

‡‡ The letter of HÉLYE (de Romans) containing his views will be found in an article entitled *Maladies régnantes.—Traitement de la dyssenterie*, Gaz. des Hôpitaux, 1859, p. 481. He maintained that the cause of dysentery is cold either acting generally, as when cold weather comes on after hot, or locally, as when one sleeps on the ground. Hence the rational treatment is to apply heat: "Si le *froid* engendre la dyssenterie, la *chaleur* la guérit. Souvent, dans les hôpitaux, j'ai pu constater la différence des résultats obtenus suivant que l'abdomen était ou non très-couvert. Couvrez le ventre, couvrez-le beaucoup, couvrez-le trop, couvrez le encore, voilà le traitement de la dyssenterie. Si cinq ou six épaisseurs de bonnes couvertures de laine ne suffisent point pour arrêter les coliques et le flux intestinal, mettez-en dix, quinze. * * * Il est bien entendu que l'abdomen seul doit être ainsi couvert, le reste du corps l'étant comme à l'ordinaire. L'ipéca, les purgatifs salins à faible dose, dont les praticiens retirent dans certains cas de grands avantages, ne doivent être considérés que comme des adjuvants."

application of *flannel bandages* to the abdomen had long before been brought into prominence by Whyte and McGregor, especially in connection with the treatment of chronic dysentery,* and has since enjoyed some reputation as a means of prophylaxis.

Warm applications to other parts of the body, such as heated bricks and bottles of hot water to the feet, and the hot bath, have already been sufficiently referred to in connection with the means of producing diaphoresis.† Warm *sitzbaths* may also be briefly alluded to in this place. The early attempts to medicate them with astringent herbs, which are recorded in the works of Savonarola and other authors cited by Sennertus, are now quite obsolete;‡ but the addition of anodynes has continued to find favor, and was adopted as useful by Savignac.§ This method of attempting to produce a local anodyne effect is at best uncertain, and, since we have become acquainted with the hypodermic method, must be regarded as quite unnecessary; but sitzbaths of warm water—as hot as the patient can bear—will sometimes prove useful in relieving tenesmus, though their efficiency for this purpose has undoubtedly been exaggerated.

Cold applications have also been made to the abdomen even in acute dysentery. The approval of Heubner gives an air of respectability to the Neptune's girdle of the hydropathists. Yet that physician himself testifies that the application of cold to the abdomen is not well borne by the majority of patients because it so often increases the tormina, and this fact would seem sufficient to discountenance the method.‖

Rubefacients.—Among the vast variety of cutaneous irritants which have been used for this purpose in ancient and modern times, sinapisms, camphorated liniments and turpentine stupes may be particularly mentioned. *Sinapisms*, long familiar as a domestic remedy, are particularly suited to slight diarrhœas accompanied by griping, for which they have been extensively used: they may, however, be found occasionally useful in more serious cases, and have lately acquired a fictitious importance in connection with the non-emetic use of ipecacuanha. *Camphorated liniments*, strongly commended by Lind and Blane, have been less extensively prescribed, but are still sometimes resorted to. They may be employed merely to bathe the abdomen, or a cloth saturated with the fluid may be applied as a fomentation. *Turpentine stupes*, regarded with much favor by Copland, have also had their advocates. A flannel wrung out of warm water may be sprinkled with the oil of turpentine and applied to the abdomen as long as the patient can bear it. I myself have often seen relief afforded to the cramps that accompany acute intestinal catarrhs by the application of a cloth moistened with *chloroform liniment.*¶ In the present state of our knowledge all such applications are to be regarded as mere palliatives, by which the griping pains that so often accompany the fluxes may sometimes be temporarily relieved. Their continued use in any case should depend upon the sensations of the patient.

---

* McGREGOR—p. 189, note, *op. cit.*, p. 713, *supra:* "In Egypt we gave trial to a mode of treatment which was strongly recommended to me by Dr. Whyte. It was the application of flannel bandages over the whole abdomen. In chronic cases, and in convalescents, it appeared to be of the greatest service; and, in recent cases, when the appropriate remedies were used at the same time, it appeared to shorten the cure."

† See pp. 729 and 732, *supra.*

‡ SAVONAROLA—fol. 179, *op. cit.*, p. 736, *supra*—says that some physicians use decoctions of plantain leaves, chamomile flowers, dill, oak leaves, and other astringents for this purpose. See, for other authorities, the remarks of SENNERTUS on sitzbaths—*loc. cit.*, note §, last page.

§ SAVIGNAC—p. 334, *op. cit.*, p. 630, *supra*—recommends sitzbaths, as hot as the patient can support, to be used twice a day during the acute stage of dysentery, while the tenesmus and tormina are troublesome. If simple water does not prove sufficiently calming, he adds a decoction of nightshade (morelle) or belladonna.

‖ HEUBNER—S. 543 u. 548, *op. cit.*, p. 529, *supra.*

¶ LIND—p. 263, *op. cit.*, p. 637, *supra*—used camphor dissolved in olive oil and mixed with laudanum. BLANE—p. 461, *op. cit.*, p. 637, *supra*—commends stupes "upon which thebaic tincture and camphorated spirits were sprinkled." COPLAND—Vol. I, pp. 720 and 727, *op. cit.*, p. 682, *supra. Chloroform liniment* is mentioned with approval by STILLÉ—p. 367, *op. cit.*, p. 650, *supra.* I myself have used the linimentum chloroformi, U. S. P., but prefer a mixture of one part of chloroform to three or four of soap liniment as more cleanly and equally efficacious. Of all such external applications, however, we may say with DEGNER—Cap. III, § 75, p. 187, *op. cit.*, p. 625, *supra:* "Effecerunt quod valebant, non vero quod debebant."

Blisters.—More important functions have been attributed to the use of blisters, by which it has been fondly hoped to modify favorably the progress of the intestinal inflammation both in acute dysentery and in the chronic fluxes. *Cantharides* were well known to the Greek physicians, who occasionally resorted to their vesicating powers in the treatment of disease;* the same is true of the Arabians,† but I find no positive evidence that either the Greeks or Arabians ever employed this means of producing revulsion for the relief of the alvine fluxes, and the systematic treatises on these disorders are silent as to this matter until after the beginning of the eighteenth century. Tissot, however, informs us that, when he wrote, blisters were commonly employed with great success in the treatment of dysentery; that in proportion as they acted the evacuations and pains diminished, and that he did not hesitate to employ them himself.‡

Degner vainly insisted that bloody urine was apt to follow their use;§ the new practice daily grew in popularity. Pringle applied blisters to the abdomen of his dysentery patients whenever the pains were too fixed to yield to fomentations and found that they afforded relief;|| Donald Monro followed the same practice;¶ Zimmermann declared that blisters not only act as palliatives in dysentery, but likewise contribute to the cure, and that they are useful in all obstinate alvine fluxes.** A great number of physicians have imitated these illustrious examples. Let it suffice to name Richter, Dewar, Harty, Bampfield, Annesley, Naumann, Hauff, Cambay, G. B. Wood and Stillé.†† Tissot had applied his blisters to the calves of the legs and the nape of the neck; Zimmermann to both places at once. The sacral region was the point of election with some physicians;‡‡ but the majority

* *Cantharides* are referred to in a number of passages in the Hippocratic writings; and the circumstance that they may produce strangury, both when taken internally and when applied topically, was already then well known. I may cite in illustration the treatise *De natura muliebri*, [Ed. Littré, VII, 325,] where an infusion, containing, among other ingredients, "four cantharides without their legs, wings and heads," is advised for women with lateral uterine flexion, if their menses are suppressed, and sitzbaths directed in case strangury supervenes; also *De morb. mulierum*, Lib. I, [Ed. Littré, VIII, 179,] where five cantharides, without their wings, legs or heads, enter into the composition of a pessary intended to hasten the expulsion of a dead embryo, and a warm sitzbath is directed if strangury follows its use. See also the account of the virtues of cantharides by GALEN—*De simp. med. temp. ac fac.*, Lib. XI, Cap. 1, [Ed. Kühn, XII, 363,]—who speaks of their use in cerates for the purpose of favoring the separation of diseased nails. Elsewhere he refers to their diuretic action and their power of irritating, or, as he puts it, ulcerating the bladder—*Ad Pisonem de theriaca Liber*, Cap. X, [Ed. Kühn, XIV, 248.] DIOSCORIDES—Lib. VI, Cap. 1, fol. 322, Ed. cited p. 623, *supra*—describing the poisonous effects resulting from their internal use, mentions difficulty of urination, bloody urine and symptoms resembling dysentery. ARETÆUS—*De cur. morb. diut.*, Lib. I, Cap. IV, p. 121, Ed. cited p. 684, *supra*—mentions cantharides as one of the most powerful of the local counter-irritants that may be applied to the head in epilepsy, but advises that for three days previously the patient should drink milk as a protection to the bladder, which cantharides are apt to injure. See, also, PAULUS ÆGINETA—Lib. VII, Cap. 3, Vol. III, p. 153. *op. cit.*, p. 624, *supra*, and the commentary of Dr. ADAMS on this passage, where it is shown that the species usually employed by the ancients was the *mylabris cichorii* or *m. füsselini*.

† Thus SERAPION—Cap. 431, fol. 193, *op. cit.*, p. 806, *supra*—declares that cantharides frequently enter into the composition of ointments; and speaks of their use in removing diseased nails and clavi, as well as in diseases of the skin: they are also applied locally to cancerous ulcers; they possess putrefactive, calefacient and ulcerative properties.

‡ For an account of the introduction of blisters into modern practice, see the learned essay of FRID. HOFFMANN—*De vesicantium et fonticulorum circumspecto in medicina usu*, Opera, T. VI, p. 67, Ed. cited p. 681, *supra*—in which, however, I find no mention of their use in the alvine fluxes. TISSOT—T. II, p. 26, *op. cit.*, p. 625, *supra*—writes: "L'on emploie aujourd'hui, avec un grand succès, les emplâtres de vésicatoires, et il est certain que dans plusieurs cas, à mesure qu'ils agissent, les évacuations diminuent, les angoisses se dissipent et les forces augmentent; aussi je ne balance jamais à les faire appliquer." I may add that, according to ZIMMERMANN—see note *, p. 838, *supra*—RESTAURAND had used blisters in obstinate diarrhœas and dysenteries in the previous century; but our library does not afford me the means of verifying this statement.

§ DEGNER does not deign to mention blisters in his work on dysentery, but in his *Relatio historica de casu singulari, quo per mercurium sublimatum, in emplastro adplicatum, mors inducta fuit*, appended to his work—p. 345, *op. cit.*, p. 625, *supra*, also p. 216 of the first edition—speaking of the absorption of the ingredients of plasters by the skin, he writes: "Testante hoc solo emplastro vesicatorio, quod, si nimia quantitate, aut nimis sæpe adplicatum fuit, mictum cruentum insecutum fuisse, observationes docent."

|| PRINGLE—p. 284, 1st Ed. cited p. 693, *supra*—sometimes "used only a warm plaister, with a fifth part of the emplastrum epispasticum added to it." I find this remark on use of blisters repeated in his 3d Ed., p. 243, and his 4th Ed., p. 282, in both of which the blistering plaster appears in the clause just cited as "a fourth part," but the passage is wanting in the 7th Ed.

¶ DONALD MONRO—p. 78, *op. cit.*, p. 625, *supra*.

** ZIMMERMANN—Cap. X, S. 421, *op. cit.*, p. 648, *supra*: "Blasenpflaster sind aber nicht nur ein linderndes, sondern auch ein heilendes Mittel in der Ruhr, in welcher sie bey ausserordentlichen Fällen, gleichwie in den übermässigen Durchbrüchen der Faulfieber, und überhaupt in allen hartnäckigen Bauchflüssen fürtreffliche Dienste thun." Further on—S. 470—he remarks that the honor of having first thoroughly investigated the use of blisters in malignant dysentery belongs to HIRZEL of Zurich and TISSOT.

†† RICHTER—Bd. I, S. 103, *op. cit.*, p. 731, *supra*; H. DEWAR—*Obs. on diarrhœa and dysentery*, &c., London, 1805, p. 134; HARTY—p. 231, *op. cit.*, p. 732, *supra*; BAMPFIELD—pp. 133 and 210, *op. cit.*, p. 682, *supra*; ANNESLEY—Vol. II, pp. 281 and 369, *op. cit.*, p. 621, *supra*; NAUMANN—Bd. IV, Abth. 2, S. 80, *op. cit.*, p. 645, *supra*; HAUFF—S. 428, *op. cit.*, p. 534, *supra*; CAMBAY—p. 589, *op. cit.*, p. 550, *supra*; G. B. WOOD—Vol. I, p. 724, *op. cit.*, p. 671, *supra*; STILLÉ—p. 367, *op. cit.*, p. 650, *supra*.

‡‡ I make this statement with regard to the practice of TISSOT on the authority of ZIMMERMANN—S. 424, *op. cit.*, p. 648, *supra*. The application to the sacral region is spoken of by both NAUMANN and HAUFF—*loc. cit.*, last note.

have followed the example of Pringle, and applied them to the abdomen, selecting as far as possible the most tender or painful point.

During the last fifty years there has been a growing tendency among the advocates of the use of blisters to limit their application to the more advanced stages of acute dysentery and to the chronic fluxes. Simultaneously there has been a growing disposition to avoid them altogether. Bankier, who still adhered to their use in what he considered suitable cases, has recited the inconveniences of large blisters in grotesque language.* Vogt made light of the benefits to be derived from these or any other external applications. Morehead was averse to large blisters, but thought small ones, two or three inches square, occasionally useful when applied over a tender or indurated point. Savignac gave sinapisms the preference for the purpose of allaying the tormina of acute dysentery, and after persistently trying blisters in chronic dysentery, abandoned them because he never saw them do any good.† Not a few of the practitioners who have made use of them during local epidemics of dysentery have found, as Brandon did, that they exert little or no influence over the progress of the majority of the cases in which they are employed;‡ while others laud them at least for the relief of pain and tympanites.§

It must be admitted that the general tenor of clinical experience is not favorable to the exaggerated hopes of benefit from the application of blisters that some have entertained. Moreover, the old speculations, by which their supposed power of curing internal phlegmasiæ was formerly explained, are now quite abandoned, and it is difficult, in the present state of our knowledge, to bring forward any plausible arguments in support of the view that the intestinal lesions can be materially modified by their influence in either acute or chronic cases. While such doubts exist the physician will hardly care to increase the risk of strangury, already existing, during the acute stage of dysentery by applying blisters at that time; and even in subacute and chronic conditions they are less and less employed by modern practitioners except as palliatives for the relief of pain, or in cases believed to be complicated with general or local peritonitis. In these latter complications their alleged usefulness is at least intelligible; and whether they modify the progress of the inflammation or not, they certainly often serve to relieve the pain. In military hospitals, however, it is best to avoid them, especially during the prevalence of gangrene among the wounded; nor should they ever be applied to scorbutic patients, or to those suffering from typhous conditions, lest the blistered surface should slough.‖

It has been recommended that, in order to escape the danger of producing strangury, the vesication should be made by strong *aqua ammonia* instead of cantharides;¶ but this

* BANKIER—p. 137, *op. cit.*, p. 637, *supra:* "Now the application of such immense blisters on the bellies of young people is a thing of no small moment, for they excite much constitutional disturbance, nay, they are not without danger in grown up persons, and had such a large one been applied over the abdomen of Job himself, it must ere it had healed have worn out his patience even if that had been as large as the fish which swallowed Jona; I have seen musquito bites for some men to contend against, but what are they to such a large blister?"

† VOGT—S. 194, *op. cit.*, p. 645, *supra:* "Es wird aber mit allen diesen so viel beliebten Dingen niemals viel ausgerichtet." MOREHEAD—p. 308, *op. cit.*, p. 657, *supra.* SAVIGNAC—p. 336, *op. cit.*, p. 620, *supra.*

‡ W. C. BRANDON—*Epidemic dysentery, as it prevailed in a portion of Floyd County, Georgia, in the Autumn of* 1851, Southern Med. and Surg. Jour., Vol. VIII, 1852, p. 139.

§ See, for example, C. C. HOWARD—*Remarks on dysentery*, same Jour., Vol. XI, 1855, p. 79. He thinks them useful also in the later stages of the disease, and is of the opinion that "very few cases of dysentery ought to be permitted to terminate fatally without their having been used." I have been unable to ascertain the extent to which blisters were employed in the fluxes during the civil war. Few of the reporters refer to their use: see, in Section II, the reports of BROWN—p. 81, *supra*—and WHITE—p. 85. On the other hand, the supplies of cantharides purchased for issue during the war were colossal, viz: 113,479 ounces of the powder and 473,789 ounces of the cerate, that is, about 3½ tons of the first and over 14½ tons of the second.

‖ As to this danger BARRALLIER—p. 775, *op. cit.*, p. 603, *supra*—remarks: "Les vésicatoires calment momentanément les douleurs, mais cette amélioration est passagère et très-souvent compensée par des accidents sérieux; sous l'influence dépressive où sont placés les dysentériques, il n'est pas rare de voir survenir des érysipèles qui s'étendent rapidement et peuvent déterminer la gangrène des parois abdominales. En résumé, nous dirons que les vésicatoires sont rarement utiles dans la dysenterie aiguë, et que leur action est douteuse et souvent fâcheuse dans la dysenterie chronique."

¶ This application has been advocated, among others, by A. FALOT, whose work I have been unable to see, and cite from BARRALLIER—*loc. cit.*

method is still more likely to cause sloughing ulcers. The same is true of pustulation with *tartar emetic*, which some have employed as a means of counter-irritation in dysentery, while pustulation with *croton oil* is perhaps less objectionable.*

Inunctions with *mercurial ointment* have already been sufficiently noticed; all the objections to producing the constitutional impression of mercury by the internal administration of the preparations of mercury during the progress of the fluxes apply also to its external use. Inunctions with *iodine ointment* and painting the abdomen with *tincture of iodine* have been resorted to to a limited extent in the chronic fluxes; it appears rational to suppose that these applications may sometimes produce good results, particularly in cases complicated with chronic peritonitis,† but further experience is required to determine the degree of benefit that can actually be obtained in this way.

* Pustulation with tartar emetic and by croton oil are among the means of counter-irritation mentioned by VOGT—*loc. cit.*, last page. CORNUEL—p. 147, *op. cit.*, p. 615, *supra*—lauded the former application especially in dysenteries complicated with ascites. Both have been praised with exaggeration by D. F. RENNIE—*Summary of views respecting a new mode of treating small pox and eruptive fevers generally, with a notice of the train of events which led to its adoption; also a few observations respecting the application of the principles involved in the cure of dysentery*, (dated Tien-Tsin the 23rd March, 1862,) in Surgeon D. F. RENNIE'S *Views on the nature and treatment of certain diseases*, Military Department Press, 1862. The application of croton oil in dysentery is mentioned with approval by COPLAND—*loc. cit.*, note ¶, p. 839, *supra*.

† The application of iodine ointment to the abdomen in chronic peritonitis has been recommended, among others, by G. B. WOOD—Vol. I, p. 859, *op. cit.*, p. 671, *supra*: see, also, Ed. of 1847, Vol. I, p. 695; and painting with tincture of iodine by BAUER—S. 395, *op. cit.*, p. 687, *supra*.

INDEX OF SUBJECTS.

Page.

Abdomen, external applications to the 837
Abdominal organs, lesions of, in subjects dead of non-ulcerative intestinal inflammation 316
Abdominal organs, lesions of, in subjects dead of diphtheritic dysentery 459
Abdominal organs, lesions of, in subjects dead of chronic intestinal ulceration 516
Abdominal tenderness in acute diarrhœa 272
Abdominal tenderness in acute dysentery 384
Abdominal tenderness in chronic dysentery 492
Abscess, hepatic; see hepatic abscess.
Abscess, perineal 385
Acari in the stools 371
Acari supposed to cause dysentery 370
Acari supposed to cause exanthemata 368
Acarus dysenteriæ 370
Acarus scabiei 368
Acetate of ammonia, solution of 732
Acetate of potash as a diuretic 731
Acid, carbolic 821
Acid, carbolic, clysters 834
Acid, muriatic 811
Acid, nitric 811
Acid, nitric, application to rectal ulcers 831
Acid, nitro-muriatic 812
Acid, nitrous 812
Acid, phosphoric 814
Acid, salicylic 821
Acid, salicylic, clysters 834
Acid, sulphuric 810 and 812
Acid, sulphuric, clysters 834
Acids, mineral 810
Acids, vegetable 814
Aconite 824
Acute diarrhœa, coexistence of cholera morbus 287
Acute diarrhœa, coexistence of continued fever 288
Acute diarrhœa, coexistence of dysentery 287
Acute diarrhœa, coexistence of inflammatory affections of the respiratory organs 288
Acute diarrhœa, coexistence of malarial fever and chronic malarial poisoning 287
Acute diarrhœa, coexistence of other diseases with 286
Acute diarrhœa, coexistence of scurvy and the scorbutic taint 288
Acute diarrhœa, convalescence from 290
Acute diarrhœa, definitions of the books 271
Acute diarrhœa, influence of season and region 290
Acute diarrhœa, initial epidemics of 286
Acute diarrhœa, occurrence of similar cases in groups 285
Acute diarrhœa, opportunities for post-mortem examination comparatively infrequent in civil life 270
Acute diarrhœa, post-mortem appearances 292
Acute diarrhœa, progress and termination 289
Acute diarrhœa, regarded by some as a mere symptom 270
Acute diarrhœa, seat of lesions 266
Acute diarrhœa, symptoms 272
Acute diarrhœa, varieties of, recognized by the Arabians, the Nosologists and others 273
Acute diarrhœa, what is included under the designation 266
Acute dysentery, catarrhal; see simple inflammatory dysentery.
Acute dysentery, comparative frequency of, among white and colored troops 430
Acute dysentery complicated by diphtheria 414
Acute dysentery complicated by erysipelas 409
Acute dysentery complicated by inflammation of the respiratory organs 406
Acute dysentery complicated by malarial fevers 398

Page.

Acute dysentery complicated by parotitis 414
Acute dysentery complicated by rheumatism 406
Acute dysentery complicated by scurvy or the scorbutic taint 406
Acute dysentery complicated by typhoid and typho-malarial fever 403
Acute dysentery complicated by tubercular diarrhœa 409
Acute dysentery, other complications 414
Acute dysentery, diphtheritic, sketch of symptoms 350
Acute dysentery, influence of region 414
Acute dysentery, influence of season 427
Acute dysentery, ancient investigation of its morbid anatomy 433
Acute dysentery, modern investigation of its morbid anatomy 438
Acute dysentery, post-mortem appearances 432
Acute dysentery, recovery without medical treatment 349
Acute dysentery, two varieties of 338
Acute dysentery, use of the term, in this work 337
Acute and chronic cases of diarrhœa and dysentery, comparative number and mortality of 4
Adenoid tissue of the intestine, histology of 318
Adenoid tissue of the intestine in catarrhal inflammation 326
Adenoid tissue of the intestine in diphtheritic dysentery 463
Air, corruption of, an alleged cause of dysentery 644
Albumen in dysenteric stools 359
Albumen in the urine in chronic dysentery 494
Albumen in the urine in diphtheritic dysentery 386
Albumen, solution of, in the treatment of dysentery 664
Alcoholic drinks an alleged cause of fluxes 620
Alcoholic beverages in the treatment of fluxes 660
Alcoholic liquors in the treatment of fluxes 661
Alexandrine school, pathological anatomy of 433
Algoid cells of J. H. Salisbury 373
Alimentation, faulty, as a cause of the fluxes 599
Alimentary canal, permeability of the entire, by clysters 836
Alum 769
Amœba coli 371
Amyloid degeneration of the intestines 333 to 335
Amyloid degeneration of the intestines in chronic dysentery 563
Amyloid degeneration of the tubercular intestine 596
Analysis of autopsies, intestinal catarrh 309
Analysis of autopsies, acute dysentery 453
Analysis of autopsies, chronic fluxes 521
Anguillula stercoralis and A. intestinalis 372 and 757
Animal food, spoiled 627
Animalcular contagion, doctrine of 367
Animated or verminous putridity of Christian Langius 370
Anise 814
Anodynes other than opium 750
Antagonism, supposed, between belladonna and opium 754
Antagonism, supposed, between tubercular disease and dysentery 577
Antimony 689
Antimony as a diaphoretic 730
Antimony and potassium, tartrate of 691
Antiseptic clysters 833
Antiseptic remedies 821
Appetite in acute dysentery 348
Appetite in chronic dysentery 492
Aqua ammonia as a vesicant 841
Aqua dysenterica 730
Aqua epidemica 730
Aqua theriacalis 729
Argyria 780
Armenian bole 762 and 785
Arnica 822

Diarrhœa, tubular, microscopical examination of the membranous matters passed ---- 366
Diarrhœa, tubular, symptoms ---- 364
Diarrhœa, tubular, synonyms ---- 363
Diascordium ---- 737
Diet, errors of, as a cause of the fluxes ---- 622
Diet for patients laboring under fluxes ---- 658
Diet, sudden changes in, as a cause of fluxes ---- 630
Digestion, disorders of, in chronic dysentery ---- 492
Diphtheria a cause of death in non-ulcerative intestinal inflammation ---- 315
Diphtheria as a complication of dysentery ---- 414
Diphtheritic dysentery, appearance of the body after death 456
Diphtheritic dysentery, lesions observed in other organs besides the alimentary canal ---- 456
Diphtheritic dysentery, symptoms ---- 350
Diphtheritic inflammation, artificial production of ---- 480
Diphtheritic inflammation of the intestinal mucous membrane in acute dysentery ---- 443
Diphtheritic pseudomembrane in dysentery, histology of ---- 462
Diphtheritic sloughs in dysentery, granular metamorphosis of ---- 473
Diphtheritic sloughs in dysentery, invasion of, by bacteria and micrococcus ---- 473
Diphtheritic sloughing of the intestines in acute dysentery 446
Diphtheritic ulcers formed in the intestine during acute dysentery ---- 448
Diphtheritic ulcers of the intestine, mode in which they extend ---- 481
Discharges on surgeons' certificate for diarrhœa and dysentery ---- 3
Discharges for disability in hospitals, effect on reported mortality ---- 15
Discrimination between diarrhœa and dysentery, diversities of opinion ---- 5
Dissection; see post-mortem appearances, morbid anatomy and autopsies.
Dissection, human, by Herophilus and Erasistratus ---- 433
Dissection, human, by the Alexandrine school ---- 433
Dissection, human, not practised by Celsus or the Roman physicians ---- 434
Dissection, human, not practised by Galen or subsequent Greek physicians ---- 434
Dissection, human, not practised by the Arabian physicians ---- 434
Dissection, human, revived in the 14th century ---- 435
Dissection practised by the ancient Egyptians ---- 432
Dissections of dysenteric subjects in the 16th, 17th and 18th centuries ---- 435
Distilled liquors an alleged cause of dysentery ---- 621
Distinction between diarrhœa and dysentery ---- 271
Distoma hæmatobium ---- 372
Diuretics ---- 733
Dover's powder ---- 732
Drinks, alcoholic ---- 661
Drinks, diluent ---- 662
Drinks, feebly nourishing ---- 662
Drinks, fermented, an alleged cause of fluxes ---- 620
Drinks, fermented, in the treatment of fluxes ---- 660
Drinks for patients laboring under fluxes ---- 658
Drinks, non-fermented, an alleged cause of fluxes ---- 621

Page.

Drinking water for patients laboring under fluxes 658
Dropsy complicating chronic dysentery 497
Drying clysters 829
Drying remedies 785
Dysenteria benigna and d. maligna 345
Dysenteria flens and dysenteria facta 345
Dysenteric lesions as described by Aretæus and Archigenes 433
Dysenteric miasm, discussion of 645
Dysenteric stools, contagion of 647, 649 and 650
Dysenteric légère and d. intense 346
Dysentery, acute; see acute dysentery.
Dysentery as described by Hippocrates 336
Dysentery, bilious 392, 394 and 395
Dysentery, bloody, four varieties of Galen 337
Dysentery, catarrhal 338 and 348
Dysentery, chronic; see chronic dysentery.
Dysentery, complications of 388
Dysentery, contagion of 646
Dysentery, convalescence after 349, 352 and 503
Dysentery, definitions of 336
Dysentery, diphtheritic 338 and 350
Dysentery, epidemic and endemic, associated with malarial fevers 400
Dysentery, epidemics of, in the United States 421
Dysentery, geographical distribution of, in the United States 416
Dysentery, hepatic 392
Dysentery prevailing simultaneously with diarrhœa 287
Dysentery, pseudomembranous or croupous inflammation of the intestinal mucous membrane in 344
Dysentery, rheumatic, of Alexander of Tralles 340
Dysentery, red and white 346
Dysentery, relation of, to age and sex 431
Dysentery, second attacks of 431
Dysentery, sporadic and epidemic 346
Dysentery, sthenic and asthenic 346
Dysentery, stools in; see stools, dysenteric.
Dysentery, subdivisions proposed by medical writers 347
Dysentery, synonyms 336
Dysentery, the three grades of Galen 345
Dyspeptic conditions as a cause of fluxes 630

Earths, medicinal 762 and 785
Ecchymosed spots; see purpura-like spots.
Eggs 677
Egyptians, ancient, dissections by 432
Emaciation in chronic dysentery 493
Emaciation in dysentery 388
Emaciation in subjects dead of chronic dysentery 529
Emaciation in subjects dead of diarrhœa 314
Emaciation in subjects dead of diphtheritic dysentery 456
Emetia 703
Emetics 689
Endemic influences as a cause of fluxes 643
Endothelial layer of Debove 321
Endothelioid elements of intestinal submucosa, changes of, in diphtheritic dysentery 468 and 469
Endothelioid elements in the submucosa of tubercular intestines 596
Enemata; see clysters.
Enteritis, attempt to reconcile pathological anatomy with the doctrines of the Nosologists 268
Enteritis, attempts at an anatomical classification 270
Enteritis, British and American writers who have followed the views of Cullen 267
Enteritis, conception of Pinel 268
Enteritis, confusion as to its signification 267
Enteritis, glândular, (entérite folliculeuse) 270
Enteritis, limitation by Broussais 268
Enteritis, membranous 363
Enteritis, number of cases and deaths during the civil war 2
Enteritis, the two species of Cullen 267
Epidemic and endemic dysentery associated with malarial fevers 400
Epidemic influence as a cause of fluxes 644
Epidemics of diarrhœa, initial 286
Epidemics of dysentery among the civil population of the United States 421

Epithelioid cells in tubercle 592
Epithelium, intestinal 320
Epithelium, intestinal, in Asiatic cholera 327
Epithelium, intestinal, in catarrhal inflammation 326
Epithelium, intestinal, fate of, in diphtheritic dysentery 463
Ergot 822
Erysipelas a complication of dysentery 409
Exanthemata viva, speculationsof Nyander and Linnæus 370
Exposure as a cause of fluxes 640
External medication 837

Fæces, normal, contain multitudes of low vegetable forms 278
Fæces of dogs fed on bones 665
Farinaceous articles of food 666
Fatal cases of diarrhœa and dysentery, with accounts of the morbid appearances observed 101 to 264
Fats in the alimentation of patients laboring under fluxes 668
Fatty stools; see stools, fatty.
Fennel 814
Fermented drinks 660
Fever in catarrhal dysentery 348
Fever in diphtheritic dysentery 351
Fevers, continued, complicating diarrhœa 288
Fevers, intermittent, complicating chronic dysentery 495
Fevers, intermittent, complicating diarrhœa 287
Fevers, malarial, complicating acute dysentery 398
Fevers, remittent and continued, complicating chronic dysentery 496
Fevers, typhoid and typho-malarial, complicating acute dysentery 403
Fish 678
Fistula in ano complicating chronic dysentery 499
Flannel bandages 839
Flatus in diarrhœa and dysentery 488
Flux, hepatic 392
Fluxes, classification of 265
Fluxes, periodical, old observations 399
Fluxes prevalent in marshy districts, as observed by Hippocrates 399
Follicular ulceration, analysis of autopsies 521
Follicular ulceration of the large intestine in acute dysentery 441
Follicular ulceration of the large intestine in chronic dysentery 515
Follicular ulceration of the intestines, histology of 566
Fomentations 837
Food for patients laboring under fluxes 662
Fowler's solution 823
Frankincense 815
Frequency of the stools in diarrhœa 285
Fresh vegetables and fruits 678
Frogs'-spawn stools 356 and 375
Fruit juices, drinks made from 679
Fruits an alleged cause of fluxes 624
Fruits and vegetables beneficial in fluxes during the civil war 626
Fruits, use of, during fluxes 678
Fumigations, alcoholic 732
Fumigations, hot 729

Galls 761 and 765
Gallic acid 768
Gangrenous stools 360
Gases, intestinal, composition of 489
Gases, intestinal, early analyses of 488
Gases, intestinal, in chronic dysentery 491
Gases, intestinal, in disease 491
Gases, intestinal, in health, origin of 490
Gases that escape per anum in health, composition of 490
Gatinaria's syringe 825
Gelatin 674
General hospitals; see hospitals, general.
General management of those sick with fluxes 656
Gentian 795
Geographical distribution of diarrhœa and dysentery according to the United States census reports 418
Geographical distribution of diarrhœa and dysentery in the United States Army in time of peace 417

Page.

Geographical distribution of dysentery in the civil population of the United States ---- 416
Geological formation, its relation to the etiology of fluxes ---- 643
Giant-cells in tubercle ---- 589
Ginger ---- 814
Girdle-sore, tubercular, of the intestines ---- 580
Glands of Lieberkühn ---- 318
Glands of Lieberkühn invade the closed follicles ---- 328
Glandular origin of contagious diseases ---- 652
Glass of antimony, cerated ---- 690
Glycerine ---- 824
Glycerine clysters ---- 837
Goblet-cells, alleged formation of pus corpuscles in ---- 327
Goblet-cells (Becherzellen) of the intestinal mucous membrane ---- 320
Granular metamorphosis of tissue elements in the diphtheritic sloughs, acute dysentery ---- 473
Grapes ---- 680
Guaiac ---- 824
Guarana ---- 824
Gum water ---- 662

Hæmorrhage from the bowel during diphtheritic dysentery, conditions of its occurrence ---- 482
Hæmorrhage from the bowels in dysentery ---- 357
Hæmorrhage from the bowels in other diseases than dysentery ---- 357
Hæmorrhoids complicating chronic dysentery ---- 499
Hard bread an alleged cause of fluxes ---- 629
Heart, irritable, in chronic dysentery ---- 491
Heart and pericardium, lesions of, in subjects dead of chronic dysentery ---- 533
Heart and pericardium, lesions of, in subjects dead of diphtheritic dysentery ---- 458
Heart and pericardium, lesions of, in subjects dead of non-ulcerative intestinal inflammation ---- 315
Heart-clot in subjects dead of non-ulcerative intestinal inflammation ---- 316
Heart-clots, a supposed consequence of the scorbutic taint ---- 545
Heart-clots as a supposed cause of death ---- 544
Heart-clots, cyst-like forms ---- 540
Heart-clots, early literature of ---- 538
Heart-clots formed during life, and post-mortem coagula ---- 540
Heart-clots in subjects dead of chronic dysentery ---- 537
Heart-clots in subjects dead of diphtheritic dysentery ---- 458
Heart-clots, supposed connection with endocarditis ---- 540
Heat, dry ---- 732
Heat, external, in the treatment of fluxes ---- 729
Hellebore, white ---- 689 and 703
Hepatic abscess as a complication of dysentery ---- 396
Hepatic abscess as a complication of dysentery among natives of tropical climates ---- 551
Hepatic abscess as a complication of dysentery during the civil war ---- 584
Hepatic abscess as a complication of dysentery in Cochin China, Algeria, Egypt, &c ---- 550
Hepatic abscess as a complication of dysentery in India ---- 549
Hepatic abscess as a complication of dysentery in temperate climates ---- 552
Hepatic abscess as a complication of dysentery in the civil population of the United States ---- 553
Hepatic abscess as a complication of dysentery; etiology ---- 551
Hepatic abscess, distinction between pyæmic and tropical ---- 555
Hepatic abscess in chronic dysentery ---- 499
Hepatic abscess in subjects dead of chronic dysentery ---- 517
Hepatic abscess in subjects dead of diphtheritic dysentery ---- 459
Hepatic abscess, symptoms of ---- 396
Hepatic abscesses, diagnosis between small multiple and large single ones ---- 397
Hepatic complications in dysentery ---- 392
Hepatic dysentery ---- 892
Hepatic flux ---- 392
Hiccough during dysentery ---- 388
Histological methods employed at the Museum in the study of the diseased intestines ---- 321
Histology of the normal intestine ---- 317
Histology, pathological, of chronic dysentery ---- 563
Histology, pathological, of the diphtheritic intestine ---- 461

Page.

Histology, pathological, of the inflamed intestines ---- 325
Hope's mixture ---- 812
Horsford ration ---- 627
Hospitals, general, case books of ---- 101 and 102
Hospitals, general, discharges from ---- 15
Hospitals, general, northern and southern, comparative mortality ---- 10
Hospitals, general, transfers from one to another ---- 15
Humors, vicious, an alleged cause of fluxes ---- 632
Huxham's tincture of bark ---- 798
Hydrocyanic acid ---- 757
Hyoscyamus ---- 750
Hypnotics other than opium ---- 750
Hypnotics; see also narcotics.

Ileus complicating diarrhœa ---- 391
Ileus complicating dysentery ---- 389
Ileus complicating dysentery, sloughing of the intussusceptod bowel ---- 390
Indian home guards, diarrhœa and dysentery among ---- 4
Indications of the humoral pathology ---- 687
Indicatio causalis ---- 688
Indicatio morbi ---- 688
Indicatio symptomatica ---- 688
Indigestion during diarrhœa ---- 272
Indigestion during acute dysentery ---- 387
Indigestion during chronic dysentery ---- 492
Infection; see contagion.
Infectious diseases said to be caused by low vegetable forms 282
Inflamed intestines, histology of ---- 325
Inflammation, non-ulcerative, of the intestines ---- 296
Inflammation of the intestinal mucous membrane without ulceration in acute dysentery ---- 440
Inflammation, diphtheritic, artificial production of ---- 480
Inflammation, diphtheritic, in acute dysentery ---- 443
Inflammation, non-ulcerative, of the intestinal mucous membrane in acute dysentery ---- 440
Inflammation, pseudomembranous or croupous of intestinal mucous membrane ---- 344
Inflammations of the respiratory organs complicating acute dysentery ---- 406
Inflammations of the respiratory organs complicating chronic dysentery ---- 498
Inflammations of the respiratory organs complicating diarrhœa ---- 288
Influence of region on the number of cases and deaths from diarrhœa and dysentery ---- 9
Influence of season on the prevalence and mortality of diarrhœa and dysentery ---- 18
Injections; see clysters.
Inoculation experiments ---- 282
Inorganic impurities of drinking water ---- 600
Insomnia during dysentery ---- 388
Intestinal concretions ---- 354
Intestinal gas; see gases.
Intestinal inflammation, non-ulcerative, in acute dysentery 440
Intestinal mucous membrane, lesions of, in dysentery compared to membranous and ulcerous cynanche by J. P. Frank ---- 343
Intestinal stricture after dysentery ---- 501
Intestine, large, diminished calibre of ---- 313 and 515
Intestine, large, perforation of, in chronic dysentery 523 and 527
Intestine, large, perforation of, in diphtheritic dysentery ---- 451
Intestine, small, intussusception of ---- 313
Intestine, small, intussusception of, in subjects dead of chronic dysentery ---- 528
Intestines, amyloid degeneration of ---- 333
Intestines, amyloid degeneration of, in chronic dysentery ---- 563
Intestines, amyloid degeneration of, in tubercular ulceration ---- 596
Intestines, histology of ---- 317
Intestines, histology of chronic non-ulcerative inflammation ---- 563
Intestines, histology of cyst-formation in the ---- 563
Intestines, histology of follicular ulceration of the ---- 566
Intestines, histology of ulceration unconnected with the follicles of the ---- 573
Intestines, inflamed, histological changes in the ---- 325

Perforation of the large intestine in diphtheritic dysentery 454
Periodical fluxes observed by the Greeks and Arabians ---- 399
Periodical fluxes as observed in the 16th century and later 399
Pericardium; see heart.
Perinæal abscess ---- 385
Peritoneal bands and adhesions after dysentery ---- 510
Peritonitis complicating chronic dysentery ---- 497
Peritonitis complicating dysentery ---- 388
Peritonitis complicating non-ulcerative inflammation of the intestines ---- 314
Peritonitis, lesions of, in subjects dead of acute dysentery ---- 455
Peritonitis, lesions of, in subjects dead of chronic dysentery 546
Permeability of the entire alimentary canal by clysters ---- 836
Persimmon tree ---- 766
Peruvian bark; see cinchona bark.
Philonium ---- 735
Phthisis complicating chronic dysentery ---- 498
Pills, cynoglossus ---- 751
Pills of Ségond ---- 715
Pilulæ lunares ---- 778
Pleuritic lesions in subjects dead of chronic dysentery ---- 533
Pleuritic lesions in subjects dead of diphtheritic dysentery 457
Pleuritic lesions in subjects dead of non-ulcerative intestinal inflammation ---- 315
Plasters ---- 837
Plates illustrative of the lesions of non-ulcerative inflammation of the intestinal mucous membrane, citation of ---- 297
Plates illustrative of the pathological anatomy of dysentery, citation of ---- 441
Pneumonia complicating acute diarrhœa ---- 288
Pneumonia complicating acute dysentery ---- 406
Pneumonia complicating chronic dysentery ---- 498
Pneumonic lesions in subjects dead of chronic dysentery ---- 532
Pneumonic lesions in subjects dead of diphtheritic dysentery ---- 457
Pneumonic lesions in subjects dead of non-ulcerative intestinal inflammation ---- 315
Poisoning falsely ascribed to subnitrate of bismuth ---- 791
Poisoning, lead ---- 783
Poisoning, silver ---- 779
Portal congestion as a cause of fluxes ---- 634
Post-mortem appearances of acute diarrhœa ---- 292
Post-mortem appearances of acute dysentery ---- 432 and 410
Post-mortem appearances of chronic dysentery ---- 510
Post-mortem appearances of tubercular ulceration of the intestines ---- 579
Potassa, bitartrate of ---- 707
Potassa, chlorate of ---- 824
Potassium, bromide of ---- 760
Potatoes ---- 666
Priapi ---- 821
Prisoners of war held by the Confederates, prevalence of diarrhœa and dysentery among the ---- 31

Page.

Statistical tables:
Total number of cases and deaths from diarrhœa and dysentery among white and colored troops ... 2
Total number among white troops for each year, with the annual ratio to strength and number of cases to each death ... 6
The same for colored troops ... 7
Annual number of cases and deaths from the several forms of diarrhœa and dysentery among white troops ... 7
The same for colored troops ... 8
Annual number of cases and deaths from diarrhœa and dysentery in each of the three regions, with ratio to strength and number of cases to each death for white troops ... 9

Page.
Statistical tables—continued:
Annual number of cases and deaths from diarrhœa and dysentery in each of the three regions, with ratio to strength and number of cases to each death for colored troops 10
Prevalence of diarrhœa and dysentery in the several departments of the Atlantic region 17
The same for the Central region 18
Number taken on sick report each month with diarrhœa and dysentery among white troops, expressed in ratio per 1,000 of mean strength 19
The same for colored troops 23
Monthly mortality from diarrhœa and dysentery expressed in ratio per 1,000 of mean strength for white troops 20
The same for colored troops 24
Monthly ratio of cases of diarrhœa and dysentery to strength in the Confederate and Federal Armies of the Potomac from July 1, 1861, to March 31, 1862 27
Cases and deaths from diarrhœa and dysentery in the Andersonville Prison hospital 32
Number of cases and deaths from diarrhœa and dysentery among Confederate prisoners of war at the chief prison depots 38
Number taken on sick report each month with acute diarrhœa among white troops, expressed in ratio per 1,000 of mean strength 290
The same for colored troops 291
Tabular statement of the prevalence of acute dysentery among white troops, expressed in ratio per 1,000 of strength 414
The same for colored troops 415
Tabular statement of the mortality of acute dysentery among white and colored troops, expressed in ratio per 1,000 of strength 415
Diarrhœa and dysentery in the United States Army, 1829 to 1859, inclusive 417
Average annual prevalence and mortality of diarrhœa and dysentery in the United States Army, 1839 to 1859 418
Number of deaths from diarrhœa, dysentery and enteritis in every 100,000 living persons, according to the census reports of 1850, 1860 and 1870 419
Number of deaths from diarrhœa and dysentery in every 100,000 living persons, according to the census reports of 1850, 1860 and 1870 420
Annual number of deaths from dysentery in Boston from 1811 to 1838 422
Annual number of deaths from dysentery in New York City from 1805 to 1836 422
Annual number of deaths from dysentery in Philadelphia from 1807 to 1840 422
The same from 1840 to 1860 421
Annual number of deaths from dysentery in the State of Massachusetts from 1841 to 1860 423
Annual number of deaths from dysentery in Hartford, Connecticut, from 1847 to 1854 423
Annual number of deaths from dysentery in the State of Rhode Island from 1853 to 1860 423
Annual number of deaths from dysentery in Baltimore from 1836 to 1860 424
Total number of deaths in the United States from diarrhœa, dysentery and enteritis, according to the census reports of 1850, 1860 and 1870 427
Number of cases taken on sick report each month with acute dysentery among the white troops, expressed in ratio per 1,000 of strength 428
The same for colored troops 428
Frequency of diarrhœa and dysentery in the United States Army in time of peace for each quarter of the year 429
Deaths from diarrhœa and dysentery in spring, summer, autumn and winter, according to the census of 1850 429
Monthly number of deaths from dysentery, according to the census reports of 1860 and 1870 429
Monthly number of deaths from diarrhœa, according to the census reports of 1860 and 1870 430
Ratio of deaths from diarrhœa, dyentery and enteritis per 100,000 living persons, according to the census reports of 1850 and 1870 430

Page.
Statistical tables—continued:
Ages of those who died of dysentery, according to the census reports of 1850, 1860 and 1870 431
Sexes of those who died of dysentery, according to the census reports of 1850, 1860 and 1870 431
Admissions from hepatitis and dysentery in two Bombay hospitals 556
Stomach, lesions of, in subjects dead of chronic dysentery 525 and 528
Stomach, lesions of, in subjects dead of diphtheritic dysentery 456
Stomach, lesions of, in subjects dead of non-ulcerative inflammation of the intestines 314
Stools as modified by calomel 274
Stools, dysenteric 353
Stools, dysenteric, accidental matters derived from the food and medicines taken 375
Stools, dysenteric, albumen in 359
Stools, dysenteric, bacteria and other low vegetable forms in 367
Stools, dysenteric, blood and bloody serum in 357
Stools, dysenteric, bodies resembling frogs' spawn or boiled sago grains 356 and 375
Stools of acute diarrhœa, general character of 272
Stools of acute diarrhœa, chemical examination of 278
Stools of acute diarrhœa, color of 274
Stools of acute diarrhœa, frequency of 285
Stools of acute diarrhœa, microscopical examination of 278
Stools of acute diarrhœa, odor of 283
Stools of acute diarrhœa, quantity of 285
Stools of acute diarrhœa, rapid putrefaction of 285
Stools of chronic diarrhœa, algoid cells of J. H. Salisbury 373
Stools of chronic diarrhœa, yeast plant of J. H. Salisbury 373
Stools, dysenteric, corpora pingula 357 and 376
Stools, dysenteric, feculent matters in 353
Stools, dysenteric, fragments of pseudomembrane and necrosed mucous membrane in 359
Stools, dysenteric, fungi of Baly 373
Stools, dysenteric, indigested starchy matters 375
Stools, dysenteric, mucus and pus in 355
Stools, dysenteric, mucus and pus in, confounded with fat by the Greeks 356
Stools, dysenteric, shreds and fragments of membrane recognized by ancient and modern physicians 361
Stools, dysenteric, usually alkaline 359
Stools, fatty 356 and 376
Stools, fatty, chemical analysis of the fat 382
Stools, fatty, during milk diet 383
Stools, fatty, in healthy individuals 380
Stools, fatty, quantity of fat passed 381
Stools, fatty, references to cases of 381
Stools, fatty, supposed connection with disease of the pancreas 378
Stools, fatty, views of Everard Home and others 377
Stools, fatty, views of Felix Plater and others 377
Stools, fatty, views of Mérat and others 377
Stools, fatty, views of the Greek physicians 376
Stools, fatty, when the bile is diverted from the intestinal canal 379
Stools, fatty, without disease of the liver or pancreas 380
Stools, fatty, without pancreatic disease 379
Stools, gangrenous, in dysentery 360
Stools, lienteric, fungi in 487
Stools, lienteric, in acute diarrhœa 277
Stools, lienteric, in chronic dysentery 486
Stools of chronic dysentery, bacteria and other low vegetable forms in 487
Stools of chronic dysentery, blood in 486
Stools of chronic dysentery, mucus in 486
Stools of chronic dysentery, number of 488
Stools of chronic dysentery, pus in 487
Stramonium 756
Strangury in acute dysentery 395
Strangury rare in chronic dysentery 494
Stricture of the intestine after dysentery 504
Stricture of the intestine after dysentery unknown to the ancients 505
Stricture of the intestine after dysentery, earlier observations of 505

Page.
Stricture of the intestines after dysentery, cases in medical literature 508
Stricture of the intestines after dysentery, observations of Rokitansky 506
Strigmenta 361
Strychnia 807
Styrax 815
Sudden death during chronic dysentery 502
Sudorifics; see diaphoretics.
Sugar 667
Sulphate of magnesia 706
Sulphate of soda 706
Submucous connective tissue of the intestine, histology of 318
Submucous connective tissue of the intestine, pathological histology of, in diphtheritic dysentery 468
Submucous connective tissue of the intestine, pathological histology of, in intestinal tuberculosis 595
Suppositories, anodyne 827
Suppositories vomited by the mouth 836
Suprarenal capsules, condition of, observed in subjects dead of diphtheritic dysentery 461
Swelled bellies 497
Symptoms of acute diarrhœa 272
Symptoms of acute dysentery 348
Symptoms of chronic dysentery 483
Symptoms of diarrhœa connected with intestinal tuberculosis 578

Tamarinds 704
Tannin 766
Tapioca 666
Tartar emetic 691
Tartar emetic struck from the Supply Table of the Army 690
Tartar emetic, pustulation by 842
Tea 660
Tenderness, abdominal, in dysentery 384
Tenesmus from various local causes 338
Tenesmus, vesical 385
Tenesmus, vesical, rare in chronic dysentery 494
Terminations of acute diarrhœa 289
Theriaca 730
Thrombi invaded by micrococcus from the diphtheritic sloughs 479
Tinctura antiphthisica 781
Tobacco clysters 837
Tongue in chronic dysentery 493
Tonics 795
Tonics, mineral 810
Tonics, vegetable 795
Tormentil 765
Tormina in dysentery 383
Tormina, cessation of, before death 384
Tormina, Greek opinion as to its value in diagnosticating the seat of intestinal ulceration 383
Torula-like cells in normal fæces 280
Torula-like forms in the stools of acute diarrhœa 280
Transfers from hospital to hospital, effect upon the reported mortality 15
Treatment of diarrhœa and dysentery 654
Trichina spiralis 628
Tubercles of the lungs, early anatomical investigations of 575
Tubercles of the lungs in subjects dead of chronic dysentery 535
Tubercles of the lungs in subjects dead of diphtheritic dysentery 458
Tubercles of the lungs in subjects dead of non-ulcerative intestinal inflammation 315
Tubercular diarrhœa complicating acute dysentery 409
Tubercular disease of the intestines, iconography of 582
Tubercular ulceration of the intestines, analysis of autopsies 585
Tubercular ulceration of the intestines, diarrhœa connected with 575
Tubercular ulceration of the intestines, descriptions of, in medical literature 576
Tubercular ulceration of the intestines, morbid anatomy of 579
Tubercular ulcers of the intestines, histology of 586
Tubercle cells 592

Page.
Tubercle corpuscles 596
Tubercle granulations, cheesy metamorphosis of 595
Tubercle granulations, histology of 588
Tubercle granulations in the intestinal submucosa, histology of 593
Tubercles, intestinal, etiology 597
Turpentine 815
Turpentine-emulsion clysters 837
Turpentine stupes 839
Turpentine, oil of 816
Tympanites 492
Tympanites during the chronic fluxes 491
Typhoid fever, lesions of, embraced by Aretæus and Archigenes in their conceptions of dysentery 434
Typhoid fever, lesions of, embraced by Bonetus and Morgagni in their conceptions of dysentery 435
Typhoid lesions of Peyer's patches associated with the lesions of chronic dysentery 524
Typhoid lesions of Peyer's patches associated with the lesions of diphtheritic dysentery 455

Ulceration of the intestine supposed by Stoll to be rare in dysentery 342
Ulceration of intestines in dysentery denied by Van Helmont 811
Ulceration of the intestines, follicular, histology of 566
Ulceration of the intestines unconnected with the solitary follicles, histology of 573
Ulceration of the large intestine, extensive, from diphtheritic dysentery 520
Ulcers, diphtheritic, cicatrization, histology of 482
Ulcers, diphtheritic, in acute dysentery 448
Ulcers, follicular, cicatrization, histology of 573
Ulcers, follicular, in acute dysentery 441
Ulcers, follicular, in chronic dysentery 515
Ulcers, intestinal, unconnected with the follicles in chronic dysentery 515
Ulcers, non-follicular, cicatrization, histology of 574
Ulcers of undetermined origin in chronic dysentery 525
Unrecorded and erroneously reported cases of flux 2
Urea, decomposition of, in the intestines as a cause of fluxes 633
Urine in chronic dysentery 494
Urine in dysentery 386
Urine, dysenteric, albumen in 386
Usnea humani cranii 824

Vapor of chloroform by the rectum 829
Vegetable acids 814
Vegetable astringents 765
Vegetable tonics 795
Vegetable forms, low, as causes of the various infectious diseases 282
Vegetable forms, low, transported by the circulation 282
Vegetable forms, low; see bacteria, micrococcus, torula.
Vegetables beneficial in fluxes during the civil war 626
Vegetables, use of, during fluxes 678
Venesection during fluxes 680
Veratrum viride 824
Vesical catarrh 385
Vesical tenesmus 385
Voice in chronic dysentery 493
Vomiting during dysentery 387

Wandering corpuscles in the intestinal epithelium 321
Wandering corpuscles, increased number of, in the adenoid tissue of the inflamed intestines 326
Wandering corpuscles, increased number of, in the submucous connective tissue of the inflamed intestine 325
Wandering corpuscles, swarm of, in the adenoid tissue of the mucous membrane and submucous connective tissue, diphtheritic dysentery 467
Warm applications to the abdomen 838
Warmth, dry, to the abdomen 838
Water, alkaline, an alleged cause of the fluxes 606
Water, bad, as a cause of the fluxes 599
Water, bad, as a cause of the fluxes, views of the older Army Surgeons 600
Water, bad, purification of, as practised by the Greeks and Arabians 599

Page.

Water, barley, gum, and rice ---- 662
Water, boiled or distilled, vainly used to escape fluxes ---- 615
Water, brackish, an alleged cause of fluxes ---- 608
Water, cold, an alleged cause of fluxes ---- 618
Water clysters ---- 834
Water contaminated by cemeteries as a cause of fluxes ---- 611
Water contaminated with animal organic matters as a cause of fluxes ---- 610
Water contaminated with decomposing organic matters as a cause of intestinal catarrh and dysentery ---- 401
Water contaminated with fæcal and other animal matters during the civil war ---- 617
Water contaminated with sewage a cause of fluxes ---- 612
Water contaminated with vegetable organic matters an alleged cause of fluxes ---- 609
Water, drinking, for patients laboring under fluxes ---- 658
Water, hard, an alleged cause of fluxes ---- 606
Water, iced, used with impunity ---- 620
Water, impure, a cause of fluxes ---- 616
Water, impure, a cause of typhoid fever ---- 616

Page.

Water, rain, vainly used to escape fluxes ---- 615
Water, river, an alleged cause of fluxes ---- 614
Water, selenitic, an alleged cause of fluxes ---- 606
Water, soda, iced, used with impunity ---- 620
Water, stagnant, as a cause of fluxes ---- 599
Water with inorganic substances in solution an alleged cause of fluxes ---- 605
Water with inorganic substances in suspension an alleged cause of fluxes ---- 600
Watermelons ---- 679
Wax ---- 663
Whey ---- 664
Wine ---- 660

Yeast fungus in the lienteric stools ---- 487
Yeast plant, views of J. H. Salisbury ---- 373
